must fay that the description of its state is by no means agreeable to what we have observed. The powers of this electric matter are no more benumbed or enervated (it is a very unphilosophical phrase), than if it were in a conducting body at the same distance from the opposite coating. If coatings be applied to a block of glass of two or three inches in thickness, and if the electrication be so moderate that it would not sly from the one coating to the other when the glass is removed—no sensible difference will be found between the electricity of the two coatings with or without the glass. The electric matter in the side A has not its powers engourd; they are balanced by the powers of the side B.

But how will Mr de Luc explain the charging a pane negatively? How will he bring off a quantity of electric matter, greater (according to his own account) than what will be benumbed on the other fide? Nay, we must ask, where does he find it? Is there a quantity already benumbed there? What is to revive it?

Let us now confider a little the conditution of the ingredients of this electric fluid, by which all these things are brought about. And in doing this, let us banish, when possible, all figurative language; and, in the precise and dry phraseology of dynamics, let us speak of the motion of single particles of the electric fluid, deferent fluid, and electric matter. By expansive power, must certainly be meant fuch a power as that by which air, gases, inflamed gunpowder, steam, and the like, enlarge their bulk, and which is clearly manifested as a mechanical preffure, by burfting vessels, impelling bullets or pistons, &c. as well as by the actual enlargement of the bulk of the fluid. We have no other indications of its being a force; and therefore our notions of its mode of acting must be derived folely from what we understand of this power in air or the other sluids. Newton's Principia are our authority for faying, that all that we know of it is, that it acts as a number of corpufcles would act, which repel each other with a force inversely proportional to their distances; this action not extending beyond the adjoining corpuscle, not even to the fecond. We know a good deal of the propagation of pressure and progressive motion through fuch a fluid, when it is confined in a veffel, or fyltem of veffels, of any form, and fome few fimple circumstances which take place in the elaftic undulations which may be excited and propagated through it. We have but a very indistinct notion of the motions which one mais of such a fluid will produce in another, mass, when both are at liberty to expand. This is very indiffinct; but we are certain that it will be like the motion of two maffes of air blown or driven againa each other. Now these electric fluids, by their expansive powers, must act like those others with which we are more familiarly acquainted. And here we venture to fay, that the appearunces in electricity are fo far from being like thefe, that we cannot imagine any thing more remarkably different. We shall mention but one thing. Every mark that we have for the presence of elearic fluid obliges us to grant, that in an overcharged body it is crowded into the external furface, fo that the quantity has little or no relation to the quantity of matter in any body, but merely to its furface. This is quite unlike air, or any other expansive fluid, which is uniformly distributed through the whole space comprehended by the furface which bounds it. We never faw any thing

like Areams of this electric fluid, impelling or any way acting on each other, except in the transference by fparks; be given if we pretend to explain. Now the tendency and there it was indeed like the motions of air, for it was not electric fluid, nor electric matter, but electrified air.

Let us next confider the tendencies by which the relations of these expansive sluids to other bodies are produced, and the electric motions are faid to be explained. We observe that Mr de Luc avoids the use of the words attraction and repulsion, so much employed by the British philosophers. He considers these tendencies as determinate impulsions, and adopts the doctrine of Le Sage of Geneva, who has not only laid Newton under great obligations. by a mechanical explanation of gravity, but has also explained expansion, elasticity, chemical affinity, and all specific tendencies, to the satisfaction of the most eminent mathematicians. To such only Mr de Luc professes to address himself, who are not contented with a doctrine which supposes bodies to act where they are not. But, unfortunately, Mr le Sage has never obliged the world with this explanation. We are not most eminent mathematicians; but we are able to prove, that Mr le Sage's favourite theorem, mentioned by Mr de Luc in § 157, 158. as demonstrated by Mr Prevost, the editor of Lucrece Neutonien, is a complete dereliction of the first principles of Mr le Sage, and is also incompatible with mechanical laws. Mr de Luc should have given a demonstration of the theorem on which all his system rested; otherwise it is only re-

viving " dixit philosophus, ergo verum."

But let us see what these tendencies perform. Mr de Luc fays, that the fluid, fetting out from a body by its expansive power, would move in a straight line with inconceivable velocity, and would immediately desert even this globe, were it not deslected by its tendency to other bodies. We do not fee whence this immense velocity is derived. But let it go off; it is deflected from its rectilineal course by its tendency to fome conducting body, which it reaches, but cannot, or does not, enter; and therefore must continually circulate round it, as the planets circulate round the fun, following its outline, if not too abrupt, but flying off from all points in the direction of the axis of the point, &c. Here we are at home; for this is a plain dynamical problem of central forces. All that we shall fay on this head is, that Mr de Luc has certainly not confidered the planetary motions with attention, when he hazarded this very comprehensive proposition. If he will take the trouble to do this, he will fee that every part of it is inconfiftent with the acknowledged laws of mechanism, and that the motions are absolutely impossible. Besides, we know that it will not fly off from a hundred points placed together, which is a still more abrupt outline, if they do not project beyond the brim of a pit in which they stand; yet this pit only makes the outline more abrupt. We farther believe, that no person can form to himself any distinct notion of such circulations round every conducting body; they will be more numerous, and infinitely more confused and jarring, than all the vortices of Des Cartes. How can fuch motions take place round a bunch of brass wire buried in fealing wax? Yet he must grant that they really happen there; or what prevents the electric fluid from being strained clear of all electric matter in passing thro' the air?

We would also ask, why the tendency is always from the body containing most of the fluid to that containing least? It is not enough to fay that it is so; this would only

be contriving a thing to fuit a purpose; a reason should to a distant body is to the matter in that body, without any relation to the fluid in it, or in the body from which it came.

On the whole, we cannot think this theory is any thing but telling a story of ideal beings, in very figurative language, which gives it fome animation and intercit. The different affinities, tendencies, and powers, are only ways of expressing certain supposed events, and fuited to those events; but it gives no explanation of the observed mechanical phenomena of electricity, shewing from acknowledged principles that they must be so.

What a difference between this laboured and intricate mechanism and the simple, perspicuous, and distinct theory of Æpinus! Even Mr Ruffel's explanation is more intelligible, and more applicable to the motions which are really observed. That gentleman faw the necessity of considering them as the subjects of mechanical discussion, and that all that was wanted was to find out what law of diffant action would tally with the phenomena. The Scotch philosopher was careful to warn his hearers that he only proposed a conjecture. The Swede calls his performance Tentamen Theoria, &c. and begins and concludes it with expressly faying, that it is only a hypothesis. The English nobleman calls his differtation an Attempt to explain some of the phenomena, &c. None of these philosophers call their works a SYSTEM, which comprehends all theories, whether that of Volta or of any other fuccessful inquirer.

We hope to be excused for treating so largely of this fubject. It struck us as a very proper example of the bad confequences of indulging in figurative language. It must be very seducing, when so scrupulous and so eminent a philosopher as Mr de Luc is led astray by it.

WE conclude this long article by observing, that whatever may be the fate of Mr Æpinus's hypothetical theory, his classification of the facts, and his precise determination of the mecanical phenomena to be expected from any proposed fituation and condition of the substances, will ever remain, and be an unerring direction in future experiments; and the whole is an illustrious specimen of ingenuity, address, and good reafoning. We hope to make this still more evident, when we apply it to the quiet and manageable phenomena of MAGNETISM

Pondere et mensura.

In page 580. col. 2. line 8th from the bottom, for "incomparable," read "comparable."

APPENDIX;

CONTAINING AN ABSTRACT OF MR COULOMB'S EXPE-RIMENTS.

MR COULOMB in the Mem. de l' Acad. de Paris for 1786, relates feveral experiments made for ascertaining the disposition or distribution of the electric fluid in an overcharged body. Their general refults were,

1. That the fluid is distributed among bodies accords ing to their figure, without any elective affinity to any

kind of substance.

For when a ball, or body of conducting matter, and of any shape, is electrified to any particular degree, as indica-

ted

ted by his electrometer, if it be touched by another equal and unilar body, fimilarly fituated in respect of the touching points, the electricity is always reduced to ½.

2. In an overcharged conducting body, the fluid diffuse itself entirely along the surface, without penetra-

ting into the interior parts.

The conducting body AB (fig. 37.) had pits a, b, &c. made in various parts of its furface. They were half an inch in diameter, and fome of them \(\frac{1}{70}\)th, others 20 ths, others 30 ths, &c. in depth. c represents the edge of a small circle of gilt paper, 5th of an inch in diameter, fixed perpendicularly on the end of a fine thread of gum lac. The body was electrified and touched with this little electroscope, by setting it flat down on the surface. The circle c was then presented to an electrometer which moved 90 degrees by a force not exceeding oooth of a French grain. When this contact was made with the even furface of the conductor, it was strongly electrified, and particularly when it touched any cminence, or the ends of long cylinders, &c. The paper being exceedingly thin, and placed in full contact, it may be supposed to bring off with it the quantity of fluid corresponding to that part of the furface, or rather a greater quantity. But when it was made to touch the bottom, even of the shallowest of these pits, it did not affect the electrometer in the leaft.

He demonstrates the following elementary theorem: The attraction or repulsion being supposed to be proportional to the inverse of any power m of the di-

stance; that is, being as $\frac{1}{\sqrt[3]{m}}$: if m be greater than 3, the action of all the masses of sluid which are at a finite

dicance is nothing in comparison with the action in contact; and therefore the fluid must be uniformly dissusded, in the same way as if each particle acted only on the

adjoining particles.

But if m be less than 3, for example if m be 2, as seems to be the case in electricity, the action of all the masses at a finite distance is not infinitely small in comparison with the action in contact, and the redundant stuid must go toward the surface, and no redundant stuid will be retained in the interior parts. The demonstration is to this effect.

Let A a BF (fig. 38.) be a perfectly conducting body of any shape, and let dae be a thin slice separated from the rest by the plane de; let dee be precisely equal and fimilar to dae, and let a b c be perpendicular to the feparating plane; then the action of all the particles in the thin slice dae (when estimated in the direction a b) on the particle b, must balance the action of all the rest of the sluid in the body; for b is supposed to be at rest. Now, as the law of continuity will be observed in any distribution of the sluid, through the whole body, it is plain that, by taking a b fufficiently finall, the difference of denfity at a and at c may be infinitely small; therefore the action of the fluid in dae will be infinitely near to an equilibrium with the action of dee; and the action of the fluid in the rest of the body on the particle b will be infinitely small. This cannot be, when the action of a mass of fluid at a finite diltance is not infinitely small in comparison with the action in contact, unless we suppose that the quantity of sluid at a finite diffance is also infinitely small, or nothing; that is, unless the whole redundant fluidis conflipated on the furface, and the interior parts are merely faturated.

The preceding propositions are quite analogous to propositions in Mr Cavendish's differtation in the Phi-

losophical Transactions for 1771.

In the Memoirs of the same Academy for 1787, Mr Coulomb endeavours to ascertain the density of the fluid in different bodies which touch each other. When the bodies do not differ extremely in magnitude, he determines this by the immediate application of them to the electrometer; but when one is extremely small in comparison with the other, he first determines the force of the large body, and then touches it 20 or 40 times with the small one, till the force of the large body is reduced to $\frac{1}{2}$, $\frac{1}{3}$, &c. The general refult was, that when the furfaces of the spheres had the proportion expressed in the first column of the following table, then the density in the small one had the proportion expressed by the numbers of the second column, and never attained the magnitude 2.

I	-	-			-	I.
4	-	-		-	-	1,08
16	-	-	-)	-		- I,3.
64	. 1 -		-	-		1,65.
Infin	iite	-	-	-	-	2.

This is extremely different from the proportions which obtain when the two spheres communicate by very long slender canals, which he found exactly conformable to the determinations of the theory: but in Mr Coulomb's experiments the spheres touched each other, and had no other communication.

He then endeavours to afcertain the denfity of the fluid in the different parts of the furface of their touching fpheres, in order to obtain some experimental knowledge of the distribution. He touched them (while in mutual contact) with the little paper circle, and examined its electricity by his electrometer, and made his estimation, on the supposition that it brought off one-half of the electricity of the touched part.

When the globes were equal, he found the denfity to be o in the point of contact, and fearcely fenfible till he took the paper 30 degrees from the point of contact. From this it increated rapidly to 60°; flowly from thence to 90°; and from thence to 180° it was

almost uniform. The densities were nearly

0		-	-		at	W .	11 -		00.
1	-			849	Manner	100-	10		30.
4		-			Marriage	-	- 1		60.
5	-		-	-	-	-	-		- 90.
6		-			Mill-relay	-	-	-	185.

He also found, that the more the globes differed in bulk, the more is the density changed in the small globe, and it is the more uniform in the great one, increasing rapidly from 0, at the point of contact, to about 7, and

beyond this being fenfibly uniform.

Hence we may conclude, that the electricity is diffused with almost perfect uniformity in a globe communicating with another at a great distance by a stender canal (as Mr Cavendish has demonstrated); while, from the reasoning employed before, it is probable that it is also uniformly distinct all along the canal; and therefore, that the quantities in two such globes are very nearly as the diameters, and the densities inversely as the diameters, as Mr Cavendish demonstrated, on the supposition that the shuid in the canal is incompressible.

He found that a small globe, placed between two equally large ones, shewed electricities of the same kind

4 I 2

からいかは記げ場当場のマル

with that of the other two, when the radius of the great one was not more than five times that of the middle one, but shewed no electricity when the disproportion was greater.

When three equal globes were in contact, the densi-

ty of fluid in the middle globe was $\frac{1}{1,34}$ of that of the other two. A fmall globe being removed to a very small distance from an overcharged great one, after having been in contad, showed opposite electricity in the fronting point; when a little farther off, it was neutral;

and beyond this, it was overcharged.

The diameters being 11 and 8, the fronting point of the finall one was negative till the distance was I; here it was neutral, and when it was removed farther, it was positive. When the diameters were 11 and 4, the small globe was negative till their distance was 2, where it was neutral. When the diameters were 11 and 2, the distance which rendered the small globe neutral in the fronting point was 21.

All these facts are perfectly conformable to a mathematical deduction, from the supposition that the redundant fluid is spread over the furface, and that the interior points are neutral. If any fort of doubt should remain in the minds of those who are not conversant in fuch discussions, it must be greatly removed by the fact, that it is quite indifferent whether one or both globes

be folid, or be an extremely thin shell. When an electrified body is touched with a long

coated to any thickness with lac or scaling wax, the two wires take off precifely the same quantity of electricity. This was demonstrated by touching a globe repeatedly till the electricity was reduced to 1/2.

Hence we must conclude, that the electric fluid does not form active atmospheres around bodies, by the action of whose particles in contact (mathematical or physical) the phenomena of attraction and repulsion are produced, but by the action of the fluid in the body, agreeable to the theory of Æpinus.

Such are the observations of Mr Coulomb. They are extremely valuable, because they confirm in the completest manner the legitimate consequences of the theory.

We think that the materiality of that which is transferred from place to place in the exhibition of electric phenomena, is greatly confirmed by fome observations of Mr Wilfon's in the Pantheon. When a fpark was taken from the whole of the long wire exter.ded in that vast theatre, the sensation was so different from a spark which conveyed even a much greater quantity of fluid from a pretty large, but compact, furface, that they could hardly be compared. The latt was like the abrupt twitch with the point of a hooked pin, as if pulling off a point of the fkin; the spark from the long wire was more like the forcible piercing with a needle, not very sharp, breaking the skin, and pushing it inward. We had this account from the Doctor in conversation. He ascribed it, with seeming justice, to the momentum acquired by the fluid accelerated along that great extent of wire.

ELE

wire, and by another of equal diameter and length,

Electricity, Electrometer.

Animal Electricity. See GALVANISM, in this Supplement.

ELECTROMETER, is an inftrument which mcafures the quantity of electricity in any electrified body. The most common electrometers are described in the article ELECTRICITY (Encycl.), no 27, and 182-233. A very valuable one is likewife described in nº 85. of the article ELECTRICITY in this volume; but there are still two electrometers, of which we have hitherto given no account, though they are of fuch value, that to pass them unnoticed would be unpardonable. The first, which is incomparably the most accurate and delicate instrument of the kind that we have feen, was invented by Mr Coulomb, and is adapted to ascertain the smallest quantity of redundant electricity. The fecond is a late invention of Mr Cuthbertson, the ingenious improver of the air-pump, and is employed only to incafure the charge of large jars and batteries.

ELECTROMETER, by Mr Coulomb of the Royal Aeademy of Sciences at Paris, described in the Memoirs

for 1785.

Mr Coulomb had made fome experiments in examination of Dr Hooke's theory of springs " ut tensio sic vis;" and found, that it was furprifingly exact, in regard to the force necessary for twisting elastic wires. Having suspended a nicely turned metal cylinder by a fine wire in the direction of its axis, and having given it feveral turns, and left it to regain its natural position, he observed, that it performed all its revolutions of untwifting and twifting in times precifely equal, whether these oscillations were of a few degrees, or consisted of

ELE

feveral revolutions He thence concluded, that the Elen force with which the wire endeavoured to regain its natural position was exactly proportional to its distance from it. Engaged, foon after, by order from the Minister of Marine, in an examination of the phenomena of the mariner's compass, he took this method of sufpending his needles, in order to obtain exact measures of the forces which canfed them to deviate from the magnetic meridian. He made some observations with needles fo suspended; which are highly valuable to the philosopher engaged in that study. When his success in this refearch had fully gratified his wishes, he turned his thoughts to the examination of the law of electric action by the help of an electrometer suspended in the same manner. It is constructed as follows:

ABDC (fig. 1.) reprefents a glass cylinder, 12 Pla inches in diameter and in height. This is covered by XY a glass plate fitted to it by a projecting fillet on the under furface. This cover is pierced with two round holes of 13th inches in diameter. One of them f is in the centre, and it receives the lower end of the glass tube f h, of 24 inches height, which is fixed in the hole with a cement made of fealing wax, or other electric substance. The top of this tube receives the brass collar H (fig. 2. no 3.), bored truly cylindrical, and having a small shoulder, which rests on the top of the tube. This collar is fastened with cement, and receives the hollow cylinder o (fig. 2. no 2.), to which is joined the circular plate ab, divided on the edge into 360 degrees. It is also pierced with a round hole G in the centre, which receives the cylindrical pin i (fig. 2. no 1.), having

Il ome- a milled head b, and an index io, whose point is bent down, so as to mark the divisions on the circle ab. This pin turns stiffly in the hole G, and the cylinder of turns steadily in the collar H. To the lower end of the centre pin is fastened a little pincer q, formed like the end of a port-crayon, and tightened by the ring q, so as to hold fast the suspension wire, the lower end of which is grasped by a similar pincer Po (sig. 3.), tightened by the ring r. The lower end ro is cylindrical, and it is of fuch weight as to strain the wire perfectly straight, but without any risk of breaking it. It may be made half of the weight that will just break it.

This pincer is enlarged at C, and pierced with a hole, which receives tightly the arm g C q of the electrometer. This is eight inches long, and confifts of a dry filk thread, or slender straw of some grass completely dried, and dipped in melted gum lac or fine fealing wax, and held upright before a clear fire, till it form a slender cylinder of about 10th of an inch in diameter. This occupies fix of the eight inches, from g to q: the remaining two inches is a fine thread of the lac or fealing wax, as it drains off in forming the arm. At a is a ball of pith of elder or fine cork, one-fourth or onehalf of an inch in diameter, made very smooth, and gilded. It is balanced by a vertical circle g of paper, of large dimensions, stiffened with varnish. 'The resistance of the air to this plane foon checks the oscillations of the arm.

The whole is feen in its place in fig. 1. where the arm hangs horizontally about the middle of the height of the great cylinder. In its oscillations the ball a moves round in a circle, whose centre is in the axis of the whole instrument. Its situation is indicated by a graduated circle Z O Q, drawn on a flip of paper, and adhering to the glass with varnish. The electrified body, whose action is to be observed, is another small ball of cork t, also gilt, or a brass ball well polished. This is carried by a stalk of gum lac m , inclosing a dry filk thread. This stalk is grasped by a clamp of cleft deal, or any fimilar contrivance which lies firm on the glass cover. When this ball is let down through the hole m, it stands so as to touch the ball a on the arm when that ball is opposite o on the graduated circle.

To electrify the ball t, we employ the infulating handle, fig. 4. which is a flender flick of fealing wax or lac, holding a metal wire that carries a finall polified metal ball. We touch with it fome electrified body, fuch as the prime conductor of a machine, the knob of a jar, &c. Introduce this electrified ball cautiously into the hole m, and touch the ball t with it. The ball a is immediately repelled, and goes to a distance, twisting the suspension-wire, till the force of twist exerted by the wire balances the mutual repulsion of the balls t and a.

Such is the process for examining the law of electric action. But when we would examine the action of different bodies in different states, another apparatus is wanted. This is represented by the piece cAd (fig. 5.), confishing of a plug of sealing wax A, which fits tight into the hole m, and is pierced by the wire cd, hooked at c, to receive a wire connecting it occasionally with an electrified body, and having below a polithed

The instrument is fitted for observation in the follow manner: Turn the milled button b at top, till the twist-index io is on the mark o of the twist circle. Then turn the whole in the collar H, till the ball a stands opposite to the mark o of the paper circle z OQ, and at Electrome: the same time touches the ball t or d.

The observation is made thus: The ball t is electrified as already faid, and a is repelled, and retires from t, twifting the wire, and, after a few oscillations, fettles at a distance corresponding to the repulsion. Now turn the twist-index, so as to force the ball a nearer to t. We estimate the force of this new repulsion by adding the motion of the twift-index to the angle at which the ball first rested. By turning the twist-index still more, we bring the balls still nearer, and have a meafure of another repulsion.—And thus may we obtain

as many measures as we please.

In this way Coulomb afcertained the relation between the repulsion and the distance to be the inverse duplicate ratio of the distances. He discovered the law of diffipation by air in contact, and the relation which this bears to the primitive repulsion, by observing the gradual approach of a to t as the electricity diffipates from both, and by flackening the twist-index till the ball a retires to its primitive distance. He ascertained the diffipation along imperfect conductors, and the length necessary for infulation, by completely infulating the ball t, and observing the loss by air in contact with it, and then fliding a metal rod down the infulating stalk, till the diffipation began to exceed what took place by the air alone. He examined the proportion of redundant fluid in communicating bodies, by connecting them alternately with the piece, fig. 5.; as also by electrifying one ball, and observing its repulsive force, and then tharing its electricity with another, and obferving the diminution. He examined the graduation of his electrometer, by sharing the electricity of one ball with an equal ball, which gave him the position. that indicated one-half; and, by repeating this, for onefourth, &c. in the same manner as we practised and related in Electricity (Suppl.), no 141, &c.
An example of one or two of those trials will give a

clear conception of the conclusions deduced from these

observations.

The ball t was introduced and electrified; a was repelled, and fettled at 40°; the index was twifted 140°, which brought a to 20; and the time was noted. The electricity gradually diffipated, and a came nearer to t. The index was untwifted 30°, and a retired a little beyond 200; but on waiting a few feconds, it stood exactly at 20°. The time was again noted. The inter-. val was exactly three minutes. The conclusion from the experiment was as follows:

When the ball was brought to 20°, the repulsion was evidently 140 + 20, or 160. Three minutes afterwards it was 110 + 20, or 130; and 30° were lost in three minutes, or 100 per minute. The mean force was 145. Therefore the mean loss per minute was 10. Observe also, that the primitive force corresponding to the distance was 40; and the force corresponding to

20 was 160, or inversely as 202 to 402.

But observe, that the distances were not measured by the angles, but by the chord of the angles. obliquity of action must also be accounted for; and the real lever is less than the arm, in the proportion of radius to the cofine of 1 the angle.

The wire used by Coulomb in his first experiments on the law of action was of fuch strength, that 140th of a French grain, applied at the point a, held it fast

Electrome till the twist-index was turned 360°; so that one degree corresponded to TTZJOO. of a grain. A foot of this wire weighed that of a grain. Experience having fnewn that this was a fensibility far exceeding what was necessary for the measures that he had in view, and made the inftrument too delicate for common uses, he fubflituted much fironger and fhorter wires, and recommends much smaller dimensions for the whole instrument. We have made two of only five inches in diameter and 14 inches high; the arm ag being 21 inches, and the suspension a single sibre of silk, carrying 30 grains. It is far more sensible than Bennet's gold leaf electrometer. The same influment, with a filver wire sufpenfion, and a thread of lac projecting from the end g, as an index to coincide more closely with the scale, is fufficiently nice for all experiments of measurement. is always proper to have the diameter of the cylinder double the length of the arm, that the action of the glass may not disturb the position of the arm. It is greatly improved by having a round hole in the bottom of the infirument, in which the cylinder Co of the lower pincer may hang freely: this prevents much tedious ofcillation. For ordinary experiments, for meafuring charges of batteries, and the like, a much less delicate instrument, with a suspension-wire strained at both ends, is abundantly delicate, and vaftly more manageable. The wire should extend as far below the arm as above it, and should be grasped below, by a pincer turning by a milled head in a hole at the end of a slender spring. This enables us to adjust the instrument speedily. Having placed the twift index at o, turn this lower button gently till the ball a points exactly to o che the paper circle. Even in this coarfest state we have found it more delicate, and much more exact, than the electrometer described in ELECTRICITY (Suppl.), nº 85. which was much more coftly, and liable to accidents. Coulomb's electrometer has the great advantage of wasting very little electricity; whereas Henly's, or Brookes's, or de Luc's, waste it very fast when it is intense.

We improved it greatly by taking away the apparatus with the ball t, and substituting the piece, fig. 5. for it, after changing its construction a little. Instead of the wire cd, we used the smallest glass tube that we could varnish on the inside, by drawing through it a filk thread dipped in varnish. Having varnished it with lac both within and without, a brass ball d was fixed on its lower end, and a fine wire, with a ball at top, was put down into the tube, fo as to touch the ball below. When the plug was fitted into the hole m once for all, the fituation of the ball d suffered no alteration. When delicate experiments are to be made, the upper ball c is touched by the charger, fig. 4. which electrifies d. C is immediately drawn out with a glass forceps; and thus d is left completely infulated. When external electricity, fuch as the faint electricity of the atmosphere is to be examined, the wire is allowed to remain in the tube. - N B. A fcrupulous experimenter, who may object to the straining spring recommended above, may substitute a small weight, which will be conftant in its action.

The reader will observe, that this electrometer, as hitherto managed, measures only repulsions. It is not to eafy to measure attractions with it; and Mr Coulomb was obliged to take a very circuitous method, during which a great deal of electricity was diffipated. Lasthis respect, the electrometer described in the article

ELECTRICITY (Suppl.) has the advantage; but in every Elegan other respect, Mr Coulomb's is the finest electrometer that has yet been published, giving absolute measures, and this with great accuracy. The Hon. Mr Cavendish has employed the confiruction in Lis most valuable experiments on the force of gravity (Phil. Trans. 1798, Part II.); an experiment which Newton would have been delighted with observing.

Cuthbertson's ELECTROMETER is thus described by himself in the last number of the second volume of Nicholsen's Philosophical Journal. GH (fig. 6.) is an oblong piece of wood, about 18 inches in length and fix in breadth, in which are fixed three glass supporters, D, E, F, mounted with brafs balls, a, c, b. Of these supporters E and F are exactly of the same length; but D is four inches shorter. Under the brass ball a is a long brass hook; the ball c is made of two hemifpheres, the under one being fixed to the brass mounting, and the upper turned with a groove to shut upon it, so that it can be taken off at pleasure. The ball b has a brass tube fixed to it, about three inches long, cemented on the top of F, and the fame ball has a hole at the top, of about one-half inch diameter, corresponding with the infide of the tube. A B is a straight brasswire, with a knife edged centre in the middle, placed a little below the centre of gravity, and equally balanced with a hollow brass ball at each end, the centre, or axis, refting upon a proper shaped piece of brass fixed in the infide of the ball c; that fide of the hemisphere towards c is cut open, to permit the end c A of the balance to descend till it touches the ball a, and the upper hemispliere C is also cut open to permit the end c B to ascend; i is a weight, weighing a certain number of grains, and made in the form of a pin with a broad head; the ball B has two holes, one at the top, and the other at the bottom; the upper hole is so wide, as to let the head of the pin pass through it, but to stop at the under one, with its shank hanging freely in b; k is a common Henley's quadrant electrometer; and when in use it is screwed upon the top of c.

It is evident, from the construction, that if the foot fland horizontal, and the ball B be made to touch b, it will remain in that position without the help of the weight i; and if it should by any means receive a very low charge of electric fluid, the two balls b, B, will repel each other; B will begin to afcend, and, on account of the centre of gravity being above the centre of motion, the ascension will continue till A rest upon a. If the balance be fet again horizontal, and the pin i be put into its place in B, it will cause B to rest upon b, with a pressure equal to that weight, so that more electric fluid must be communicated than formerly before the balls will feparate; and as the weight in B is increafed or diminished, a greater or less quantity of electric fluid will be required to effect a separation.

When this instrument is to be applied to a jar, or battery, one end of a wire L must be inserted into a hole in b, and the other end into a hole of any ball proceeding from the infide of a battery, as M. A chain, or wire, or any body through which the charge is to pass, must be hung to the hook at m, and carried from thence to the outfide of the battery, as is reprefented by the line N. k must be forewed upon c, with its index towards A. The reason of this instrument being added, is to shew, by the index continuing to rife, that the charge of the battery is increasing, because the

Ellipfe.

arone other part of the inftrument does not act till the battery

has received its required charge.

It is almost needless to observe that this instrument confifts of three electrometers, viz. Henley's electrometer, Lane's discharging electrometer considerably improved, and Brookes's fleelyard electrometer improved likewife. By this combination and these improvements, we possess all that can be required in an electrometer for batteries and large jars; for, by k, we see the progress of the charge; by the separation of B b, we have the repulfive power in weight; and by the ball A, the discharge is caused when the charge has acquired the strength proposed.

In the journal from which this abstract is taken, the reader will find some curious experiments made with batteries by means of this electrometer; but one will be sufficient to explain its use. Prepare the electrometer in the manner shewn in the figure, with the jar M annexed, which contains about 168 square inches of coating. Take out the pin in B, and observe whether the ball B will remain at rest upon b; if not, turn the adjusting screw at C till it just remains upon A. Put into B the pin, marked i, weighing 15 grains; take two inches of watch pendulum wire, fix to each end a pair of spring tongs, as is represented at G m, hook one end to m, and the other to the wire N, communicating with the outfide of the jar; let the uncoated part of the jar be made very clean and dry; and let the prime conductor of an electrical machine, or a wire proceeding from it, touch the wire L; then, if the machine be put in motion, the jar and electrometer will charge, as will be feen by the rifing of the index of k; and when charged high enough, B will be repelled by b, and A will descend and discharge the jar through the wire which was confined in the tongs, and the wire will be fused and run into balls. The ingenious author, by breathing through a glass pipe into the jar, damped it a little in the infide. Then loading B with a pin of 30 grains, he obtained fuch a charge as fused eight inches of watch pendulum wire, disposed exactly as the two inches were disposed in the former experiment. By repeating and varying his experiments, he found that double quantities of electrical fluid, in the form of a discharge, will melt four times the length of wire of a certain diameter.

ELEPHAS, the ELEPHANT. See Encyclopedia; where the natural history of this huge and fagacious animal is detailed at confiderable length. Since that article was published, we have feen the third volume of the Afiatic Refearches, in which fome important queftions, which we were then obliged to leave in uncertainty, feem to be decided by John Corfe, Efq They relate, 1st, To the mode in which elephants copulate; which Buffon afferts (and in proof of his affertion adduces the structure and position of the generative organ in the female) to be performed while that female remains recumbent on the back; but which Mr Corfe infifts, from ocular evidence, takes place after the manner in which the horse copulates with the mare. 2d, To the method of receiving nourishment from the mother; which is not, as Buffon avers, by the trunk, but by the mouth, which fucks the dug, while the trunk of the young animal grasps it round to press out the milk. 3d, To the period of their going with young; which

Mr Corfe conceives cannot be lefs than two years; Elephantiwhereas Buffon and Pennant assign only nine months for the geltation of their young. His reasons for this supposition are unanswerable, and shall be given in his

" As far as I know, the exact time an elephant goes with young has not yet been ascertained; but it cannot be less than two years, as one of the elephants brought forth a young one, twenty one months and three days after she was taken. She was observed to be with young in April or May 1738, and the was only taken in January preceding; fo that it is very likely she must have had connection with the male fome months before she was secured, otherwise they could not have discovered that she was with young, as a fœtus of less than fix months cannot well be supposed to make any alteration in the fize or shape of so large an animal. The young one, a male, was produced October 16, 1789, and appeared in every respect to have arrived at its full time. The gentleman to whom it belongs examined its mouth a few days after it was brought forth, and found that one of its grinders on each fide had partly cut the gum."

When Mr Corfe wrote his memoir, the young elephant was active and well, and beginning to eat a little grafs. In Africa the Hottentots feed on the elephant; and M. Vailant declares, that an elephant's foot, when baked in their manner, is a most delicious morfel.

ELEPHANTIASIS (fee Medicine, nº 352. Encycl.) is one of the most dreadful maladies with which the human race is anywhere afflicted. It is not indeed common, if it be found at all, in the temperate climates of Europe; but it is frequent in the East and West Indies, where it too often baffles the skill of the ablest physicians. In the second volume of the Asiatic Refearches we have the following prescription for its cure:

" Take of fine fresh white arsenic one tólá, or 10; grains; of picked black pepper fix times as much: let both be well beaten at intervals for four days successive. ly in an iron mortar, and then reduced to an impalpable powder in one of stone with a stone pessle, and thus completely levigated, a little water being mixed with them. Make pills of them as large as tares or fmall pulse, and keep them dry in a shady place. One of those pills must be swallowed morning and evening with fome betel leaf, or in countries where betel is not at hand, with cold water: if the body be cleanfed from foulness and obstructions by gentle cathartics and bleeding before the medicine is administered, the remedy will be speedier."

This prescription, we are told, is an old secret of the Hindoo physicians, which they consider as a powerful remedy against all corruptions of the blood, whether occasioned by the elephantiasis or the venereal discase, which they call the Persian fire, and which they apply likewife to the cure of cold and moist dittempers, or palfy, distortions of the face, relaxation of the nerves, and fimilar difeafes. As the Hindoos are an ingenious and scientific people, it might be worth some European. phyfician's while to make trial of this ancient medicine in the West Indies, where the elephantiasis or kindred diseases prove so frequently fatal.

ELEVATION, in architecture, denotes a draught or description of the principal face or side of a building; called alto its upright or orthography.

ELLIPSE, or ELLIPSIS, is one of the conic fec-

Enamelling.

Ellipfoid tions, popularly called an oval; being called an ellipfe or ellipfis by Apollonius, the first and principal author on the conic fections, because in this figure the squares of the ordinates are less than, or defective of, the rectangles under the parameters and abscisses. See Consc Sections, Encycl.

ELLIPSOID, is an elliptical spheroid, being the folid generated by the revolution of an ellipse about

either axis.

ELLIPTOIDE, an infinite or indefinite ellipfis. de. fined by the indefinite equation $ay^{m+n} = bx^m \cdot a - x^n$ when m or n are greater than 1: for when they are

each = 1, it denotes the common ellipse.

There are feveral kinds or degrees of elliptoides, denominated from the exponent m + n of the ordinate y. As the cubical elliptoide, expressed by $ay^3 = bx^2$ a - x; the biquadratic, or furfolid $ay^4 = bx^2 \cdot a - x^2$;

EMINENTIAL EQUATION, a term used by some algebraifts, in the inveltigation of the areas of curvilineal figures, for a kind of affumed equation that contains another equation eminently, the latter being a par-

ticular case of the former.

ENAMELLING OF VESSELS FOR THE KITCHEN. In the year 1779 the Society of Emulation in Paris proposed as a prize question, "To discover a composition fit for making kitchen utenfils which should be free from the difadvantages attending copper, lead, tinned veffels, glazed earthen ware, &c. which should be as strong as possible, less costly than the vessels used at prefent, and which should be able to bear the highest degree of kitchen fire, and the most sudden changes from heat to cold."

In consequence of this proposal, Mr Sven RINMAN of the Royal Academy of Stockholm, without any intention of being a candidate for the premium offered by the Society of Emulation, inflituted a fet of experiments on small vessels of copper and hammered iron, with the view of giving to them a coating of what may properly be called enamel, which should not have the defects of tinning, and which, when applied to iron, should take from it the inconveniency of rusting, and of blackening many forts of victuals when they are dreffed in it. These experiments he submitted to the academy of which he was a member; and as we think them important, we shall lay the substance of them before our readers.

The most common, and the cheapest, kind of white enamel that is to be met with in the shops (which is an opaque white glass, composed of powdered quartz, of glass of lead, and of calx of tin), was tried for coat. ing kitchen-utenfils; and he found that it was excellent for the purpose, as it produced a coating, which was not only clean and agreeable in its appearence, but poffessed likewise all the power of resisting the action of fire and of acids that could be defired. But, as it is very difficult to apply, is very dear for common use, and is befides confidered as not being capable of refifting violent blows or falls, he made various experiments with substances of less price; of which the following are certainly worthy of being related.

1. The white semi-transparent fluor spar was reduced into a fine powder, with an equal quantity of unburnt gypfum, and afterwards calcined in a strong fire with a

fully flirred. The vessel which he intended to coat, Enan having first been wetted by dipping it in water, had as much of the aforesaid powder applied to its inside, by means of a very fine filk fieve, as would adhere to it of itself, or could be made to do fo by pressing it with the finger. After this veffel had been dried and gradually heated, it was exposed to a sudden and violent heat, partly in a coal-fire, kept up by a pair of bellows (the veffel being at the fame time covered, fo that no coals or ashes could fall into it,), and partly in an affaying furnace.

In the coal-fire, and with a heat as violent as is commonly used to make copper-folder run, the mixture was melted, in about the space of a minute, into an opaque white enamel, which evenly covered the furface of the copper, and fixed itself pretty firmly to the metal; it also bore hard blows without breaking, and refisted the trials made by boiling things in it, and by applying acids to it. The forementioned mixture was also reduced into a fine powder in a glass mortar, and made into a fort of thin paste with water; it was then applied to the vessel with a small brush, an operation as easy as that of applying any other wet colouring matter. likewise tried this paste, by covering vessels with it in the same way the potters apply their common glazing for flone-ware. By both the above-mentioned processes he obtained a very fmooth coating, particularly by the latter, which is more quickly performed. When the paste is applied, the veffel should be made a little warm, so also should the paste itself.

If the conflituent parts of these two substances be confidered (that is to fay, that gypfum is compoled of calcareous earth faturated with vitriolic (fulphuric) acid, and fluor spar of a particular acid united to filiceons earth; also, that the whole, when put into the fire without the addition of any other substance, is, of all earthy or stony mixtures, that which the most easily melts into an o. paque white glass, not very brittle), and if, on the other hand, the action of acids be attended to -we shall easily conceive these substances must attach themselves firongly to copper, and that the varnish formed by them cannot afterwards be dissolved or acted upon by acids.

The greatest difficulty attending on this simple mixture is, the strong and sudden heat necessary to apply it with effect, that heat being greater than is commonly to be obtained in an affaying furnace. On that account, M. Rinman endeavoured to render it more fufible by the addition of some other substance.

Of his experiments made with this view, some failed, and others succeeded. We shall record only such as were fuccessful, and at same time attended with such moderate expence as not to preclude them from common use.

2. With the substances employed in his first experiment, which, with the author, we shall henceforth call n° 1. he mixed an equal quantity of what is called fufible glass (vitrum fusibile), composed of fix parts of lime, four of fluor toar, two of quartz reduced into a fine powder, and one tenth of a part of manganele; the whole having been calcined, and ground with water, in the manner colours are ground, he fpread it on the veffel with a brush. This mixture ran pretty well upon the copper in the coal fire; it also attached itself very ftroughy to it, and produced an enamel which was firm and hard, and seemed likely to bear wear; but white heat; the whole being, from time to time, care- it was of a dark grey colour, and without any brillian-

amel- cy. The mixture did not melt more readily in the affaying furnace.

Two parts of no 1. with one part of the fulible glass, and a quarter of a part of manganese, had nearly the same effect. This last mixture, indeed, was rather more easily melted, but it had a darker colour.

3. Eight parts of no 1. with one half of a part of borax, one quarter of a part of nitre, and half a part of manganele, were melted, in the space of ten minutes, into a brown liver-coloured glass; which, in the asfaying furnace, produced upon the copper veffel a black enamel, which had a dull furface. In other respects it was firm, even, and hard; but it did not fufficiently cover the veffel by a fingle application, nor was it capable

of refishing the action of acids.

4. One part of the brown glass mentioned in the last experiment, with three parts of no 1. became, in the affaying furnace with a red heat, almost as sluid as the last, and had an even and smooth surface; but it was of a dark colour, and had not any brilliancy. It was not fensibly acted upon by vitriolic (fulphuric) acid.

5. Four parts of 110 1. mixed with one half of a part of litharge, were melted in a crucible, with the help of the bellows, in five minutes, so as to become as fluid as water. This mixture, during the fusion, emitted a fmell of fulphureous acid, and formed an opaque glass of a straw colour; which, after being ground, as usual, and spread upon a copper vessel, produced an enamel which covered the veffel very evenly, and was without bubbles. It was likewife, perhaps, the hardest of all, but could not be melted in the affaying furnace, requiring a stronger fire kept up by the bellows. It preserved its straw colour, but without any lustre, and refifted the action of acids better than the common gla-

zing of the potters.

6. Mr Rinman mixed together equal quantities of gypfum, fluor spar, and what the potters call white lead (A), and which ferves for the basis of their glazing. This mixture, after being calcined, melted in five minutes, with the affishance of a pair of bellows, into a very white, hard, and opaque enamel, which was very eafily poured out of the crucible. This enamel, treated like the others, ran very freely, equally, and without bubbles, by the heat of the affaying furnace. It was also pretty hard and strong, but without any lustre, and had green and yellow spots, occasioned by the acids of the gypfum and fluor spar, which had acted upon the copper during the fusion of the enamel. It, however, bore melting two or three times, and then appeared of a white colour; it was but very little affected by other acids.

7. Equal parts of fluor spar, of gypsum, of litharge, and of pure flint glass, powdered and mixed together, melted in five minutes, by the help of a pair of bellows, and produced a white and hard glass, very like that of the last experiment, but rather harder. After being applied on the veffel in the usual manner, it formed, with the greatest heat of an assaying furnace, an enamel of a yellowish white colour, firm and hard, but without lustre. In order to avoid the formation of bubbles, care was taken (as ought always to be done

SUPPL. VOL. I. Part II.

in enamelling) to remove the veffel from the fire as foon Enamelas it had acquired a brilliant appearance therein, or as

foon as the enamel was completely melted.

8. Twelve parts of glass of lead, or of litharge, with eight parts of flint glass, and two of flowers of zinc, were melted, in the space of seven minutes, into a clear yellow glass, which, when used for enamelling, was difposed to form bubbles; but, by continuing the heat for a longer time, the bubbles were difperfed, and he obtained a pretty good enamel, of a yellow brown colour with a greenish cast, very hard and firm. It resisted the action of the vegetable acids, like the enamels already spoken of, but it was a little attacked by the mi-

o. He powdered and mixed together five parts of fluor spar, five parts of gypsum, two parts of minium, one half of a part of borax, two parts of flint glass, one half of a part of calx of tin, and only one twenty-fifth of a part of calx of cobalt. This mixture was melted in a crucible in fix minutes, by help of the bellows, and produced an opaque glass of a pearl colour, a little inclining to blue, on account of the calx of cobalt. It was pretty hard, and, after being ground with water in the usual way, it became of a very good confistence, fo as to be very fit for spreading over vessels, to which it adhered very strongly. If any bubbles formed on the veffel during its drying, they might be rubbed down with the finger, and the whole furface rendered fmooth and even. After being warmed, and gradually heated, it was put into an affaying furnace made very hot with birch charcoal, which had been just kindled under the mussle. After a minute it melted, and began to appear brilliant; fo that he found it necessary to take out the veffel very quickly, which was already very evenly coated with a thick, and fufficiently hard, enamel, the furface of which, however, had no brilliancy.

The colour remained always inclining to green, because the copper had been a little attacked by the acids of the gyplum and fluor spar during the fulion; but in other respects this enamel was very firm, was very little hurt by flight blows, and bore very well fudden changes of heat and cold. Weak acids had no action upon it; but he had some reason to think that it would, in length of time, have been acted upon, to a certain degree, by vitriolic (fulphuric) acid. Its colour, except the forementioned shade of green, was white, with

a dull, and rather changeable, furface.

The calx of cobalt which has been just mentioned, and which Mr Rinman made use of merely with the intention of obtaining a fine colour, was prepared by faturating a folution of cobalt in aquafortis (nitric acid) with common falt, and evaporating to dryneis; by which means he obtained a fine rofe-coloured calx. A very fmall quantity of this calx, when mixed with any fusible glass, gives it a beautiful blue colour.

Of the various species of enamel, which have been described in the course of these experiments, and which may be all applied, with more or less advantage, to kitchen utenfils, the least expensive are nos 1, 2, and 5.; but they are also those which require the greatest heat. On the other hand, no 9. may be recommended

Eramel- as the most easy of fusion, and, at the same time, very durable when used for coating vessels in which victuals are to be dreffed, which is here the principal object, and is of far greater importance than the brilliant appearance refulting from the enamel generally used by artists, which however may be employed when the faving of

expence is not regarded.

· 'The enamels hitherto described are not applicable to veffels made of iron, though they may be employed to cover copper with great advantage. Iron will not indeed bear the common practice of enamellers, namely, to be put into the fire and taken out again several times; for the sparks which fly from iron, when in a hot fire, detach and carry off the enamel from the parts contiguous to those where the sparks are formed. The acids, too, of the gypfum and fluor spar, made use of in the enamels already mentioned, acted upon the iron during the fusion of the enamel, from which resulted bubbles and bare spots, which entirely spoiled the appearance of the work. Our author therefore continued his experiments with a view to discover a proper enamel for vessels made of this metal.

10. He reduced into a very fine powder, and ground together, nine parts of minium (red oxyd of lead), fix parts of flint glass, two parts of pure potalh, two parts of purified nitre, and one part of borax. This mixture was put into a large crucible, which it only half filled; he covered the crucible fo that no coals could fall into it, and gradually increased the fire under it. When the effervescence had entirely ceased, he caused the mixture to melt, by using the bellows for four or five minutes; by these means he obtained a clear and compact glass, which he poured out of the crucible upon a piece of marble. Having quenched it in water, and reduced it to a very fine powder in a glass mortar, he ground it with water to the confisence of a very thin paste. He then covered an iron vessel with it on both fides, which, after having dried and heated it by degrees, he put under a muffle well heated in an affaying furnace. The enamel melted very readily in the space of half a minute, and with a very brilliant appearance. He immediately withdrew the veffel, and let it cool: it was found to be entirely coated with a beautiful enamel of a black colour; which colour appeared to be caused by a thin layer of calcined iron, which might be feen through the transparency of the enamel.

A copper vessel having been covered with the same enamel, the fine colour of the copper was visible through the thin coat of glass; and it was as well defended from rust by this coating as it would have been by an enamel

of a stronger kind.

11. To hinder the colour of the metal from being feen through the coating he added to the mixture, used in the preceding experiment, only one hundredth part of the calx of cobalt described in no 9. The whole was melted into a beautiful blue glass; it was prepared for enamelling, and applied, in the manner before described, upon another iron vessel. The enamel proved to be smooth, thick, and brilliant, like the preceding, but it covered the vessel more perfectly; it was of a fine blue colour, with some black spots in those parts where it had been most thinly applied.

12. The glass of no 10. reduced into powder, and ground with potters white lead, of which mention has

already been made, melted with the fame facility; it Enan produced a very smooth enamel, of a grey colour, but more firm and hard than the former, and, on account of Enfie the addition made to it, of a still less price. By mixing . with the same glass a small quantity of crocus martis, he obtained a very fine enamel, of a dark red colour, not to mention other colours in it still more beautiful. The crocus martis he used in this experiment was prepared from a folution of iron in aqua regia (nitro-muriatic acid), which was evaporated to dryness, and the matter thus edulcorated and calcined.

13. In order to render the forementioned enamel more folid, and to give it what is called body, he melted together a mixture of twelve parts of flint glass, eighteen parts of minium, four parts of potash, four parts of nitre, two parts of borax, three parts of calx of tin, and one eighth part of calx of cobalt, observing always the usual precautions. He obtained a glass of a light blue colour, which, after having been ground with water, and spread upon small iron basins, or tea cups, produced, by means of a brisk fire in an affaying furnace, an enamel which was fmooth and even, and of a pearl colour. The coating was of a proper thickness, to obtain which requires a certain degree of dexterity and practice. He also tried to paint upon this enamel with what is called mineral purple (purpura mineralis), which he used with a little powdered quartz, nitre, and borax; it produced a very beautiful red colour.

Though this last mentioned composition is more beautiful when applied upon iron, and more even than the preceding, it has the difadvantage, on account of the falts which it contains, of not relifting the action of the ftronger vegetable acids, and still less that of the mineral ones. But as a vessel when coated with this enamel bears, without any injury, fudden changes of heat and cold, and also to have any greafy mixtures baked or boiled in it (even those which are of a caustic alkaline nature, or those which contain the usual weak acids which are used in the preparation of our food), it may be applied to veffels of various kinds, among others to tea cups; particularly as it is neither brittle nor fubject to crack, provided it is not exposed to violent blows. It is hardly necessary to say, that this enamel can only be applied upon vessels made of hammered iron, and not upon those of cast iron, these last being always too thick to be heated with fufficient quickness; for the greater is the space of time necessary to make the vessels red hot, the greater is the quantity of scales formed upon them, and, of courfe, the enamel becomes more injured.

Our author makes fome other judicious observations on the enamel for iron, of which he has described the composition, and says, that, independent of its use for coating kitchen utenfils, it might be made to ferve many other purpoles, fuch as preferving things made of that metal, not only from ruft, but also, as he proved by experiment, to a certain degree, from calcination.

ENCAUSTIC PAINTING. See PAINTING in this

Supplement.

ENFIELD (William, L. L. D.), well known in the learned world by feveral useful and elegant publications, was born at Sudbury, on March 29, O. S. 1741, of parents in a humble walk of life, but of very respectable characters. His amiable disposition and promifing talents early recommended him to the Rev. field. Mr Hextall, the diffenting minister of that place, who took great care of his education, and infused into his young mind that taste for elegance in composition which

ever afterwards distinguished him.

In his 17th year he was fent to the academy at Daventry, then under the direction of the Rev. Dr Ashworth, where he paffed through the usual course of inflruction preparatory to the office of the ministry; and with fuch fuccess did he cultivate the talents of a preacher, and of an amiable man in fociety, that, on leaving the academy, he was at once chosen, in 1763, minister of the very respectable congregation of Benn's

Garden in Liverpool.

In that agreeable town he passed seven of the happiest years of his life, very generally beloved and effeemed. He married, in 1767, the daughter of Mr Holland draper in Liverpool, with whom he passed all the rest of his days in most cordial union. His literary reputation was extended, during his residence in this place, by the publication of two volumes of fermons, which were very well received, and have ferved to grace many pulpits besides that in which they were originally preached. A collection of hymns and of family prayers, which he also published at Liverpool, did credit to his taste and

judgment.

About 1770, he was invited to take a share in the conduct of the academy at Warrington, and also to occupy the place of minister to the diffenting congregation there, both vacant by the death of the Rev. Mr Seddon. His acceptance of this honourable invitation was a fource of a variety of mixed fensations and events to him, of which anxiety and vexation composed too large a share for his happiness. No assiduity on his part was wanting in the performance of his various duties; but the diseases of the institution were radical and incurable; and perhaps his gentleness of temper was ill adapted to contend with the difficulties, in matter of discipline, which seem entailed on all dissenting academies, and which, in that fituation, fell upon him, as the domestic resident, with peculiar weight. He always, however, possessed the respect and affection of the best disposed of the fludents; and there was no reason to fuppole that any other person, in his place, could have prevented that diffolution which the academy underwent in 1783.

During the period of his engagement there, his indefatigable industry was exerted in the composition of a number of works, mostly, indeed, of the class of useful compilations, but containing valuable difplays of his powers of thinking and writing. The most considerable was his "Institutes of Natural Philosophy" (quarto, Johnson, 1783); a clear and well-arranged compendium of the leading principles, theoretical and experimental, of the sciences comprised under that head. And it may be mentioned, as an extraordinary proof of his diligence and power of comprehension, that, on a vacancy in the mathematical department of the academy, which the flate of the inflitution rendered it impossible to supply by a new tutor, he prepared himself, at a short warning, to fill it up; and did fill it with credit and utility, though this abstruse branch of science had never before been a particular object of his study. He continued at Warrington two years after the academy had broken up, taking a few private pupils.

In 1785, receiving an invitation from the principal

diffenting congregation at Norwich, he accepted it, Enfield. and first fixed his residence at Thorpe, a pleating village near the city, where he purfued his plan of taking a limited number of pupils to board in his house. He afterwards removed to Norwich itself; and, at length, fatigued with the long cares of education, entirely ceafed to receive boarders, and only gave private instructions to two or three select pupils a few hours in the morning. This too he at last discontinued, and devoted himself solely to the duties of his congregation, and the retired and independent occupations of literature. Yet, in a private way and small circle, few men had been more successful in education, of which many striking examples might be mentioned, and none more fo than the members of his own family. Never, indeed, was a father more deservedly happy in his children; but the eldest, whom he had trained with uncommon care, and who had already, when just of age, advanced in his professional career so far as to be chosen town-clerk of Nottingham, was most unfortunately snatched away by

a fever a few years fince.

This fatal event produced effects on the doctor's health which alarmed his friends. The fymptoms were those of angina pedoris, and they continued till the usual ferenity of his mind was restored by time and employment. Some of the last years of his life were the most comfortable: employed only in occupations which were agreeable to him, and which left him mafter of his own time; witnessing the happy settlement of two of his daughters; contracted in his living within the domestic privacy which he loved; and connected with some of the most agreeable literary companions, and with a set of the most cordial and kind-hearted friends that perhaps this island affords, he seemed fully to enjoy life as it flowed, and indulged himself in pleasing prospects for futurity. Alas! an unsuspected and incurable disease was preparing a fad and fudden change: a schirrous contraction of the rectum, the fymptoms of which were mistaken by himself for a common laxity of the bowels, brought on a total floppage, which, after a week's flruggle, ended in death. Its gradual approach gave him an opportunity to display all the tenderness, and more than the usual firmnels, of his nature. He died November 3. 1797, amidst the kind offices of mourning friends, and his last hours were peace!

Besides the literary performances already mentioned, Dr Enfield completed, in 1791, the laborious talk of an abridgment of "Brucker's History of Philosophy," which he comprised in two volumes quarto. It may be truly faid, that the tenets of philosophy and the lives of its professors were never before displayed in so pleasing a form, and with such clearness and elegance of language. Indeed it was his peculiar excellence to arrange and express other mens ideas to the utmost advantage. Perhaps, at the time of his decease, there was not in England a more perfect master of what is called the middle flyle in writing, combining the qualities of ease, elegance, perspicuity, and correctness, entirely free from affectation and fingularity, and fitted for any subject. If his cast of thought was not original, yet it was free, enlarged, and manly. What he was in the capacity of a teacher of religion, his feveral congregations will testify with grateful and affectionate rememberance. Few ministers have paid such unremit. ting attention to the perfection of their pulpit compofitions; nor was it only by detached discourses that he inculcated the truths of morality and religion, but by methodical plans of instruction, drawn up with great care and comprehension. The valuable stores of this kind which he left behind him, will not be configned to oblivion; but, it is hoped, will inform and improve numbers to whom the voice of the preacher could never have extended. In delivery, his manner was grave and impressive, depending rather on the weight of just enunciation than on the arts of oratory. Little need be added to this sketch of the moral qualities of the excel--lent man above commemorated. If moderation, compliancy, and gentleness were ever prevalent in him to a degree of excess, who that knew him will blame an excess which opened his foul to every emotion and office of affection and friendship?

This account of Dr Enfield, which is taken from the Monthly Magazine, is acknowledged by its author to be the effusion of friendship; but we believe that the panegyric, though high, is in general just. It is our duty, however, to warn our readers against placing implicit confidence in the Doctor's representation of ancient philosophy; for though we have frequently found him correct, and have therefore quoted him with approbation ourselves, we have likewise found him sometimes mistaking the sense of his authors. In a work like his, mistakes were indeed unavoidable; for when he resolved to compress the substance of Brucker's five volumes within the compass of two, he could not avoid sometimes giving what he thought the fense of the ancients, when accuracy required their very words to be given. This we believe to be the fource of those errors in his elegant history, which we have heard others un-Juftly attribute to defign; for had it been his defign to deceive, he would not furely have stored his margin with references to enable every reader to detect the deceit.

ENGINEER is the appellation of him whose profession it is to contrive or make any kind of useful engine or machine. He is denominated either a civil or military engineer, according as the objects of his profession respect civil or military purposes. See FORTIBICATION, Encycl. and MACHINE in this Supplement.

ENGONASIS, in aftronomy, the same as Hercules,

one of the northern conflellations.

ENGRAFTING. See Graffing, Encycl. where it is faid that there is little hope of producing mixed fruits by engrafting one tree upon another of the same class. We confess ourselves to be unwilling to relinquish this opinion; but it would be very unfair to withhold from the public any fact which seems to militate against it, and has come to our knowledge. We shall therefore transcribe from the Philosophical Magazine the following communication from Dr Thornton, lecturer on medical botany at Guy's Hospital, respecting a supposed Lusus natura, which he considers as the consequence of engrafting.

In the first volume of the Philosophical Transactions, No XXIX. published November 1667, you have the

following communication, intitled,

"Some Hortulan Experiments about the engrafting

of Oranges and Lemons or Citrons, whereby is produced an individual Fruit, half Orange and half Lemon, to growing together as one Body upon the fame Tree."

We have here orange trees (faith the intelligence from Florence) that bear a fruit which is citron on one fide and orange on the other. They have been brought hither out of other countries, and they are now much propagated by engrafting. This was confirmed to us (fays the editor of the Transactions of the Royal Society) by a very ingenious English gentleman, who afferted, that himfelf not only had teen, but bought of them, anno 1660, in Paris, whither they had been sent by Genoa merchants; and that on some trees he had found an orange on one branch and a lemon on another branch (which is not so remarkable as what sollows); as also, one of the same fruit, half orange and half lemon; and sometimes three quarters of one, and a quarter of the other.

In the third part of the Reports of the Board of Agriculture, among the foreign communications, we fee, with equal pleasure and aftonishment, an account of the American apple, which, by a peculiar mode of budding (A), is half fweet and half four, half white and half red, without the least contusion of the respective halves.

At Mr Mason's, florist, Fleet street, opposite the Bolt and Tun, there is a production now, September 1798, to be seen half peach and half nectarine. It has all the fostness and yellow down of the peach, and the sleek red smoothness of the nectarine; supposed to be a lusus natura, but probably is rather the sportings of art than of nature, and which perhaps will be the cause why we shall in suture see many other such vegetable wonders, which, as we see, were known to our ancestors.

ENNEADECATERIS, in chronology, a cycle or period of 19 folar years, being the fame as the golden number and lunar cycle, or cycle of the moon.

EPAULE, or ESPAULE, in fortification, the shoulder of the bastion, or the angle made by the face and slank,

otherwise called the angle of the epaule.

EPISCOPACY is a subject of which, in our own opinion, enough has been said in the Encyclopadia. We are requested however to insert 'in this place an argument additional to no 17. of that article; and we comply with the request the more readily that we find the argument, which has been suggested to us, in that very work of Dr Berkeley's which we were permitted to abridge even before our amiable friend had published it himself. The argument indeed is not new. It was, we believe, first used by Dr Wells in some controversial letters against the English differences, which were published early in the current century. Dr Berkeley adopted it from Dr Wells; and other doctors have taken it from Dr Berkeley. It is as follows:

That the apostles established two orders of ministers in the Christian church is admitted by all who contend not for the equal and common rights of Christians; and that the persons occupying the higher order, by what-

⁽A) The manner in which the extraordinary nectarine-peach first produced in this country was effected, was by inferting the bud of one fruit upon the stock bearing a different fort.

papacy ever title they were known, or however limited may have been the jurisdiction of each, possessed authority as well to ordain others as to preach the gospel and administer the facraments, is the very point on which the advocates for the divine right of presbytery infift. At the reformation, however, and for 1400 years before, there was an intermediate order of ministers between these two, known by the name of priests or presbyters, authorifed indeed to preach the gospel and to administer its facraments, but not authorifed to fend labourers of any kind into Christ's vineyard. This intermediate order therefore being, by the supposition, distinct from the two apostolical orders of ministers, must have been, at whatever period it was introduced into the church, an order of human invention; but it is from this order of ministers that the clergy of those churches, which are not Episcopal, derive all their authority to minister in holy things. The confequence is obvious.

Scotch Episcopalians are a fociety of Christians certainly as respectable, if not so numerous, as any other in the kingdom which diffents from the worship and difcipline of the established church. For many years, however, the public worship of that society was proferibed by the legislature; and there is reason to suspect that its real principles are not yet universally underflood. If this be so, it surely becomes the editors of a work in which some account is given of almost every denomination of Christians down to the novel feet which styles its members BEREANS, to do justice to the venerable remains of what was once the established church

of their native country.

That the reformation from popery was in Scotland of E. tumultuous and irregular is known to all Europe; and acy very few of our readers can be ignormal nor decency in the reformed church nor decency in NA with much address, accomher worship till James VI. with much address, accomplished the establishment of a very moderate episcopacy. To this form of church government the better part of the nation was fufficiently attached; and it continued to be the ecclefiaffical polity, supported by the state, till the grand rebellion, when it was overthrown by the partizans of the national covenant. It was restored, however, in 1662; and again abolished in 1689 by that convention which placed the Prince and Princess of Orange on the ancient throne of the Scottish monarchs.

These events are so universally known, that it is sufficient in this place barely to mention them; but there are probably many of our readers who do not know, that, during the whole period of her legal establishment, the Scotch episcopal church had no public liturgy. It appears indeed, that the first reformers made use of the English book of common prayer; and there is on re--cord fufficient evidence that John Knox himself, though he difapproved of some things in that book, had no objection either to stated forms of prayer in general, or to a subordination among the ministers of the gospel; but his fucceffor Andrew Melvil, who possessed neither his learning nor his worth, had influence enough to introduce into the church a perfect parity of miniflers, and to excite among the people a very general abhorrence of liturgical worship. So rooted indeed was that abhorrence, that, as every one knows, an attempt to introduce into the church of Scotland a book of common prayer, copied with fome alterations from that of England, produced the folemn league and covenant,

which involved in one common ruin the unfortunate Episcopacy. Charles and his darling Episcopacy. At the restoration of the monarchy, the Episeopal constitution of the church was restored, but no new attempt was made to establish the use of a public liturgy; and except at the ordina- Except at tions of the clergy, when the English forms were used, ordinations, no service book was seen in a Scottish church

For some years after Episcopacy had ceased to be the religion of the state, the deprived clergy made no alteration in their modes of focial worship. Having refused to transfer to King William that allegiance which they had sworn to King James, they were treated, during his reign, with fuch feverity, that on the Lord's day they durst not venture further than to officiate "in their own hired houses, where they received fuch friends as chose to come in unto them;" and in those small congregations, if congregations they may be called, they continued to pray, if not extempore, at least without book, till the accession of Anne to the throne of her ancestors. The attachment of that Princess, not only to the conflitution, but also to the worship of the church of England, was well known to them; and they very reasonably thought, that they could not more effectually recommend themselves to her protection than by adopting the use of the English liturgy, which the most enlightened among them had long professed to admire. It was accordingly introduced by degrees into Scotland; and an act of parliament being passed on the 3d of March 1712, "to prevent the disturbing of those of the Episcopal communion in that part of Great Bri-Introductain called Scotland, in the exercise of their religious tion of the worship, and in the use of the liturgy of the church of English li-England," that liturgy was universally adopted by the turgy. Scotch Episcopalians; and public chapels, which had hitherto been prohibited, were everywhere built, and well frequented.

That those who had refused allegiance to King William and Queen Anne should scruple to pay it to a new family, clogged as it was by fo many oaths, can excite no wonder; nor is it at all wonderful, that, for their attachment to the abdicated family, the public worship of the Scotch Episeopalians was, after the infurrection of 1715 and 1716, laid under some restraints. These, however, were neither rigorously severe, nor of long duration; and by the year 1720, their congregations were as numerous as formerly, confifting, especially in the northern counties, of men of all ranks, even such as held offices of trust under the established government, who frequented the Epifcopal chapels in preference to the parith churches.

Hitherto the Episcopalians had been safely conducted through all dangers and difficulties by the prudence of Dr Rose, the deprived bishop of Edinburgh; but soon after his death, which happened on the 20th of March 1720, divisions broke out among them, which threatened to prove more fatal to their church than any perfecution to which they had yet been subjected. For reasons which will be seen afterwards, it is proper to

trace those divisions from their source.

No native of Britain, who knows any thing of the Sources of history of his country, can be ignorant, that Dr San-division acroft, the archbishop of Canterbury, and five other bi- south Eshops, were at the Revolution deprived of their sees piscopaliby an act of parliament; because, like the Scotch bi-ans. shops, they could not bring themselves to transfer to

King

Episcopa y. King William and Queen Mary that allegiance which they had fo lately fworn to King James. As those prelates were extremely popular for the vigorous oppofition which they had given to some of the Popish projects of the late king, and as a number of inferior clergymen, of great eminence for piety and learning, were involved in the same fate with them; it need not excite great furprife, that a sweeping deprivation, which, in all its circumstances, was perhaps without a precedent in ecclefiaftical history, produced a schism in the church of England. The deprived clergy, confidering the bishops who were placed in the sees thus vacated as intruders, and all who adhered to them as schismatics, opened separate chapels under the authority of the primate and his nonjuring suffragans; and contended, that they and their adherents constituted the only orthodox and catholic branch of the church in England.

Both churches, however, made use of the same liturgy; and during the lives of the deprived prelates, there was no other apparent difference in their worship than what necessarily resulted from their paying allegiance to different sovereigns. But this uniformity was not of long duration. The bishops, who had been possessed of sees before the Revolution, were scarcely dead, when their successors, being under no civil restraint, found, in the principles which they had brought with them from the establishment, the means, not only of dividing their own little church, but likewise of sowing the seeds of dissensing among their brethren in Scotland.

* Supper of the Lord, Ensycl.

It has been observed elsewhere *, that in the church of England there are three opinions respecting the nature and end of the Lord's Supper, which, in opposition to each other, have been all patronifed by men of great eminence for theological learning. It appears, indeed, from the first liturgy set forth by authority in the reign of King Edward VI. that the reformers of that church from the errors of popery unanimously held the Lord's Supper to be a eucharistical facrifice; and this opinion, which has been adopted by great numbers in every age fince, feems to have been the most prevalent of the three among those clergy who were deprived of their livings at the Revolution. It is indeed countenanced by feveral passages in the present order for the administration of the Lord's Supper; and therefore, though there are other things in that order which cannot be easily reconciled to it, archbishop Sancrost and his suffragans, whatever their own opinions might be, chose not to widen the breach between themfelves and the establishment, by deviating in the smallest degree from the form in which they had been accustomed to celebrate that facrament. Their fucceffors, however, in office, were men of different dispositions. Confidering themselves as totally unconnected with the state, and no longer bound by the act of uniformity, one party, at the head of which was bishop Collier, the celebrated ecclesiastical historian (A), judged it proper to make fuch alterations in the communion office as might render it more fuitable to their own notions of the Lord's Supper, and bring it nearer, both in matter and form, to the most ancient liturgies of the Chriflian church.

Of the proposed alterations, some were perhaps pro. Episte v per in their circumstances; whilst others, to say the best of them, were certainly needless, if not inexpedient. They were accordingly all opposed by another powerful party of nonjurors; and the questions in dispute were referred, first to Dr Rose, the deprived bishop of Edinburgh, and afterwards to Dr Atterbury and Dr Potter, the bishops of Rochester and Oxford. What judgment the two English prelates gave in this controverfy we know not; but that of bishop Rose did him much honour. Declining the office of umpire between the parties, he recommended mutual forbearance and occasional communion with each other, according to either form; and employed a gentleman, well verfed in ecclefiaftical literature, to prove that fuch a compliance of bishops with each other's innocent prejudices was not uncommon in the pureft times.

These disputes among the English nonjurors, and the appeal which was made to Dr Rose, drew, more closely than hitherto it had been drawn, the attention of the Scotch Episcopal clergy, not only to their own liturgy, which had been authorised by King Charles I. but likewise to the most ancient liturgies extant, as well as to what the fathers of the first three centuries have taught concerning the nature of the Lord's Supper. The consequence was, that such of them as were scholars soon discovered, that the Scotch communion office approached much nearer to the most ancient offices than the English; and a powerful party was formed for re-

viving the use of it in Scotland. Had those men aimed at nothing farther, it is probable they would have met with very little opposition. Their opponents, who, in general, were less learned than they, were fo ftrongly attached to the house of Stuart, that they would have adopted almost any thing Revi fanctioned by the royal martyr's authority; but the ancie advocates for the Scotch office knew not where to stop, ges, They wished to introduce some other usages of the primitive church; fuch as the commemoration of the faithful departed, and the mixture of the eucharistic cup (See Supper of the Lord, no 2. and 3. Encycl.); and their brethren, perceiving no authority from Charles I. for these things, and being accustomed to consider them as Popish practices, a violent controversy was ready to burst forth about what every enlightened mind must confider as matters of very little importance.

That the eucharistic cup was in the primitive church mixed with a little water, is a fact incontrovertible; that the practice was harmless and decent, it is wonderful that any man should deny: but that such a mixture is effential to the factament, we cannot believe, for the reasons assigned in the article referred to; and therefore it ought surely to have been no object of contraction.

tention.

That the faithful departed were commemorated in the primitive church long before the invention of purgatory, is known to every feholar; that in those days such a commemoration tended to invigorate the faith and the charity of Christians, it would, in our opinion, be very easy to prove; and that at present every Christian prays in private for his deceased friends, we have proved

(A) This very learned, though violent man, of whom the reader will find some account in the Encyclopædia, was, with Dr Hickes and others, confecrated by the deprived prelates, for the purpose of preserving the Episacopal succession in what they confidered as the true church of England.

which we are under no apprehension (See Greek-church in this Supplement): but we see not the necessity of introducing such prayers into public worship at any period; and we perceive impropriety in doing it at a period when, from various circumstances, they may cause weak brethren to err. But those who pleaded for the revival of this practice in the beginning of the current century, were blinded by their very erudition (B); and those who opposed it seem not to have been acquainted with the workings of a benevolent and devout mind, or indeed to have known in what the essence of a prayer

The ancient ufages, however, were not the only fubjects which, on the death of bishop Rose, furnished matter for controverfy among the Scotch Episcopalians. That excellent prelate, together with the deprived archbishop of Glasgow, and the deprived bishop of Dunblain, had, from time to time, as they faw occasion, raifed to the Episcopal dignity some of the night deferving Presbyters of the church; but it was resolved, for what reason we do not very well know, that none of the new bishops should be appointed to vacant dioceses during the life of any one prelate who had poffeffed a legal establishment; so that bishop Rose, who survived all his brethren, was for several years the ecclesiastical governor of the whole Episcopal church in Scotland. On his death, therefore, though there were four bishops in Scotland, and two Scotch bishops residing in London, there was not one of those prelates who could claim to himself the authority of a diocesan over any portion of the Catholic church. This they at first unanimously acknowledged; and one of them, in the name of himself and his brethren, recommended to the clergy of the diocefe of Edinburgh to elect, after the primitive plan, a fuccessor to their late venerable diocesan. The advice was followed; the election was made, and approved by the bishops: and Dr Fullarton, the bishop

chosen, became bishop of Edinburgh, by the same means Episcopacy, and the same authority as, in the primitive church, St Cyprian became bishop of Carthage, or Cornelius

bishop of Rome.

The clergy in other districts, following the example of those in Edinburgh, diocesan Episcopacy was about to be revived throughout all Scotland upon principles purely ecclefialtical, when some of the bishops, whom Dr Rose had left behind him merely for preserving the Episcopal succession, conceived a new and very extraordinary conflitution for the Scotch Episcopal church. Whether they were envious of their colleagues, and of- College of fended that none of the elections had fallen upon them; bishops. whether they were so ignorant as not to know that diocesan Episcopacy had subsisted long before the conversion of the Roman empire, in absolute independence on the state; or that they were actuated, as there is reason to suspect, by some political principle which they could not with fafety avow; - so it was, that they opposed diocesan Episcopacy of every kind, and proposed to govern the whole Scotch church by a college of bishops. Against this unprecedented scheme the more learned bishops opposed all their influence; and being exceedingly difagreeable to the inferior clergy, it was very foon abandoned by its authors themselves, who, after fome acrimonious controversy, were glad to come to an agreement with their diocesan brethren.

Of this agreement, or convordate as it was called, the Thofe divifollowing were the principal articles: I. "That the fions healScotch or English liturgy, and no other, might be edindifferently used in the public service; and that the
peace of the church should not be disturbed by the introduction of any of the ancient usages which had lately excited such dissensions. 2. That no man should
thenceforward be consecrated a bishop of the Scotch
church without the consent and approbation of the majority of the bishops. 3. That the bishops, by a majority of voices, should choose one of their number to

prefide.

⁽B) Paradoxical as this affertion may at first fight appear, nothing is more certain than that erudition; and even science, if partially cultivated, is as Ikely to blind as to enlighten the understanding. When a man devotes all his time, and all his attention, to one pursuit, he contracts such a fondness for it, as gradually to consider it as the only valuable pursuit, which will infallibly lead to truth, and to nothing but truth; and in this diiposition of mind, he is ready to embrace the most extravagant absurdity to which it may conduct him. Of this the reader will find one very striking instance in page 547 of this volume, where the celebrated Euler appears fo devoted to his darling analysis, as to place implicit confidence in it, even when he himself seems sensible that it had led him to a conclusion contrary to common sense, and the nature of things. That Dr Bentley was a very eminent philologist, is univerfally known; that his emendatory criticisms on the Classics are often happy, no man will deny; and yet, missed by his favourite pursuits, he never pronounces more dogmatically than when the dogma which he utters is untenable. We appeal to his criticisms on Milton. Perhaps there is not a man alive who will refuse to Dr Warburton the praise of learning and ingenuity. The address with which he desects the double doctrines of the ancient philosophers, is sometimes almost astonishing; yet, misled by his own. ardour in this pursuit, he discovers hidden meanings everywhere, and has found a rational system of religion in fome of the ancient mysteries, where there is every reason to believe that nothing in reality was to be found but atheism and vice. Just fo it is with the ardent reader of the Christian fathers. If he devote all his time to the study of their writings, he not only becomes enamoured of his employment, but acquires gradually such a veneration for the character of his masters (and venerable they undoubtedly are) as renders him afraid to question any thing which they advance, and unable to diffinguish between their testimony, which is deserving of all credit, and their reasonings, which are often inconclusive. We trust it is needless to disclaim any wish to discourage, by this note, the fludy either of the Christian fathers, the Greek philosophers, philological criticism, or the modern analysis; we only wish to disfuade men of letters from devoting their whole time to any one pursuit whatever; for they may depend upon it, that fuch partial studies contract the mind. One of the most eminent mathematicians at present in England is reported to have declared his contempt of the Paradise Lost, because he found in it nothing demonstrated!

Bpifcopacy prefide in the meetings of his brethren, and to convocate fuch meetings when he judged them necessary: that this prefident should be flyled Primus Episcopus, or more shortly Primus; but that he should not posfels metropolitical power, or claim any kind of jurisdiction without the bounds of his own diocese or district. 4. That upon the vacancy of any diocefe or diffrict, the presbyters should neither elect, nor submit to, another bishop, without receiving a mandate by the Primus, iffued with the confent of the majority of his col-

> This concordate was in 1731-2 subscribed by all the bishops then in Scotland, who immediately became diocefans, and thought no more of the college fystem. It was afterwards, with a few additions, for afcertaining more precisely the prerogatives of the Primus; for regulating the conduct of fynods; for exempting bishops from the jurisdiction of other bishops, in whose districts they might chance to refide; and for preventing inferior clergymen from deferting their congregations, or removing from one district to another, without the confent of the bishops of both-thrown into the form of canons; and these canons have continued to be the code of the Scotch Epifcopal church down to the pre-

Political opinions.

The members, and more especially the clergymen of this church, had always been confidered as unduly attached to the family of Stuart; and though there was undoubtedly at first some ground for that suspicion, the writer of this article knows, from the most incontrovertible evidence, that it was continued too long, and carried by much too far. Jacobitism was imputed to the fociety as its diftinguishing tenet; but the members of that fociety have at all times contended, that their distinguishing tenets were the apostolical institution of Episcopacy, and in the exercise of those powers which are purely spiritual, the independency of the church upon the flate. In politics, indeed, they have unanimously maintained, that the only ruler of princes or legislatures is God, and not the people. They are, of course, no friends to the fashionable doctrine of resistance, which they believe to be not only condemned in express terms by Christ and two of his apostles, but to be also the fource of that anarchical tyranny which is at prefent deluging Europe with blood. They confider a limited monarchy, like that of Britain, as the most perfect form of civil government which the world has ever feen; an hereditary monarchy is infinitely preferable to one that is elective: and with respect to the title of the monarch, when they take a retrospective view of the origin of all civil governments, they cannot but look upon a permanent and unquestioned establishment as an indication of the plan and determination of Providence furnishing the best right to a crown which any modern sovereign can claim.

10 Persecution

Surely these are harmless opinions; and yet the worship of those who held them was, in 1746 and 1748, laid under fuch restraints as were calculated to produce disaffection where it did not previously exist. Two laws were then enacted against the Scotch Episcopalians; which, under the pretence of eradicating their attachment to the house of Stuart, were so contrived as to preclude such of their clergy as were willing to pay allegiance to the reigning fovereign, and to pray for the royal family by name, from reaping the smallest benefit from their loyal-

ty. The experiment was tried by some of them; of Episcopac whom one venerable person, who was never suspected of undue attachment to the house of Stuart, is still alive; but he, and his complying brethren, had their chapels burnt. and were themselves imprisoned, as if they had been the most incorrigible Jacobites. This was a kind of perfecution which, fince the Reformation, has had no precedent in the annals of Britain. A priest of the church of Rome, by renouncing the errors of Popery, has at all times been qualified to hold a living in England; a diffenting minister, of whatever denomination. might at any time be admitted into orders, and rife to the highest dignities of the English church; -but while the laws of 1746 and 1748 remained in force, there was nothing in the power of a Scotch Episcopal clergyman to do from which he could reap the smalleit benefit. By taking the oaths to government, he was not qualified to hold a living in England, or even to enjoy a toleration in Scotland; and his elerical character being acknowledged by the English bishops, he could not by those prelates be canonically reordained.

Upon the clergy, however, those laws of uncommon rigour were not long rigorously executed. After a few years, the burning of chapels, and the imprisoning of ministers, were occurrences far from frequent; but the laws to which we allude affected likewife the political Toleration privileges of fuch laymen as frequented the Epifcopal chapels; and in that part of their operation, those laws were never relaxed till 1792, when they were wholly repealed, and the Episcopalians in Scotland tolerated like other well affected diffenters from the national effa-

While Episcopacy was the established form of church Faith of government in Scotland, the clergy of that church fub. the Scotl feribed a confession of faith summed up in twenty-five church articles, which the reader will find in the history attributed to John Knox. It is sufficient to observe in this place, that in csentials it differs little from the articles of most other reformed churches; and in every thing which does not immediately relate to patisfry, it is moderate and unexceptionable; perhaps more fo than the present confession of either of the British churches. During the period which intervened between the Revolution and the year 1792, no fubfcription was indeed required from Scotch Episcopalian clergymen to any summary of Christian doctrine; but at their ordinations, those clergy solemnly professed their belief of all the canonical books of the Old and New Testaments; declared their perfuafion that those books contain fufficiently all doctrines necessary to falvation, through faith in Jesus Christ; and were obliged to read daily in their chapels the English book of Common Prayer, which contains the Apostles, Nicene, and Athanafian creeds. But now those clergymen are enjoined by act of parliament to subscribe the 39 articles of the church of England; fo that the principles of their faith are well known. No doubt there are differences of opinion among them about the fense of some of those articles; and it is well known that there are fimilar differences among the English clergy themselves: but there is every reason to believe, that the faith of the Scotch Episcopalians has, in every important point, been at all times orthodox.

We are aware, that they have been represented as unfriendly to the English service; but such a represen-

acy, tation appears to be either a wilful falsehood, or the offspring of ignorance. The only reformed liturgy that ever had the fanction of a civil establishment in

The vor-Scotland, is the Book of Common Prayer, and Adminifration of the Sacraments, and other parts of Divine Service authorised by King Charles I. In that book, the order of administration of the Lord's Supper differs in fome particulars from the English order, and is unqueftionably better adapted to the opinions of those who confider that holy ordinance either as an eucharistical sa. crifice, or as a feast upon a sacrifice. In the one or other of these lights, the Lord's Supper is viewed by a great majority of the Scotch Episcopalians; and of course the Scotch communion office is used in a great majority of their chapels: but it is not used in them all. Their bishops, who, when in England, communicate with the established church, leave the inferior clergy at liberty to use either the English or the Scotch form, as is most agreeable to themselves and to the people among whom they minister; and to filence the clamour of fymbolizing with the church of Rome, which was some years ago either ignorantly or malicioully raised against them, they altered the arrangement of the Scotch prayer of confecration, fo as not only to bring it nearer to the most primitive forms, but also to make it absolutely inconsistent with the real presence, as taught either by the church of Rome or by the Lutheran churches. On this subject, see Greek-CHURCH, no 17. in this Supplement.

Thus have we given a short view of the distinguishing principles of what must furely be considered as a and very respectable society of Christians, and the only reformed Episcopal society in that part of Great Britain called Scotland. There are, indeed, chapels in Scotland distinct from the church of which we have been treating, where the English liturgy is read by clergymen who have received Episcopal ordination either in England or in Ireland; but those chapels being all independent of such other and under the instance of such others. pendent of each other, and under the inspection of no bishop, the persons who frequent them seem to be rather Congregationalists than Episcopalians, and certainly do not constitute what can, with any propriety, be

SUPPL. VOL. I. Part II.

called an Episcopal church.

EQUANT, in astronomy, a fanciful circle, introduced into science to remove some of the defects of the Ptolemaic fystem of the universe. In this artificial fystem of epicycles and eccentric circles, the idea of circular and equable motion was by no means abandoned; but while each of the heavenly bodies revolved in its own orb, the centre of that orb was supposed to be carried at the same time round the circumference of ano ther circle. The more obvious inequalities were thus explained with a geometrical precision. With all its nice combination, however, of circles, the fystem was foon found to have defects; to remove which, the fine contrivance of the equant was introduced. Though the angular motion of a planet viewed from the earth was confessed to be unequal, a point could be conceived from which it would be feen to move with perfect uniformity. That point was made the centre of the equant, and lay at the same distance from the centre of the eccentricity on the one fide, as the earth was removed on the other. " Nothing (fays Dr Smith, from whom this account of the equant is taken) can more evidently shew, how much the repose and tranquillity of the imagination is the ultimate end of philoso- Equation phy, than the invention of this equalizing circle."

EQUICURVE CIRCLE, the same with CIRCLE of Curvature, which fee in this Supplement.

ERGETI Y'DIMMO Two Abyffinian strubs of the genus Mimosa, which see, Encycl.

ERKOOM, an Abyssinian bird, part of a large tribe, "in which (fays Mr Bruce) the greatest variety lies in his beak and horn. The horn he wears fometimes upon the beak and sometimes upon the forehead above the root of the beak." This bird is by naturalits called the Indian crow or raven; and our author, though he feems to think this classification improper, admits that he has one characteristic of the raven; he walks, and does not hop or jump in the manner that many others of that kind do; but then he at times runs with very great velocity, and, in running, very much refembles the turkey or buftard when his head is turned from

The colour of the eye of this bird is of a dark brown, or rather reddish, east, but darker still as it approaches the pupil; he has very large eyelashes, both upper and lower, but especially his upper. From the point of the beak to the extremity of the tail is three feet ten inches; the breadth, from one point of the wing to the other extended, is fix feet, and the length twentytwo inches; the length of the neck ten inches, and its thickness three inches and a half; the length of the beak, measuring the opening near the head straight to the point, ten inches; and from the point of the beak to the root of the horn, feven inches and three eighths. The whole length of the horn is three inches and a half. The length of the horn, from the foot to the extremity where it joins the beak, is four inches. 'The thickness of the beak in front of the opening is one inch and seven eightlis. The thickness of the horn in front is one inch and five eighths. The horn in height, taken from the upper part of the point to the beak, two inches. The length of the thighs feven inches, and that of the legs fix inches and five eighths. The thickness in profile seven lines, and in front four lines and a half. It has three toes before and one behind, but they are not very firong, nor feemingly made to tear up carcases. The length of the foot to the hinder toe is one inch fix lines, the innermost is one inch feven lines, the middle two inches two lines, and the last outer one two inches one line. This bird is all of a black, or rather black mixed with foot-colour; the large feathers of the wing are ten in number, milkwhite both without and within. The tip of his wings reaches very nearly to his tail; his beak and head meafured together are eleven inches and a half, and his head three inches and a quarter. At his neck he has those protuberances like the Turkey cock, which are light-blue, but turn red upon his being chafed, or in the time the hen is laying.

The erkoom, though not easily raised, slies (days our author) both strong and far. It has a rank smell, and is said in Abyssinia to feed upon dead carcases. This, however, he thinks a mistake, as he never saw it

following

following the army, nor approaching a dead carcase; and as often as he had occasion to open this bird, he found in its stomach nothing but the green scarabeus or beetle It builds in large thick trees, always, if it can, near churches; has a covered neft like that of a magpie, but four times as large as the eagle's. It places its nest firm upon the trunk, without endeavouring to make it high from the ground: the entry is always on the east side.

El'ON is a place which, on account of its college, should not be omitted in a repository of arts, sciences, and literature; and as no notice is taken of it in the Encyclopadia, we shall deviate for once from the plan which we had laid down for this Supplement, and which is, not to admit into it descriptions of places in our own island that may be visited by the greater part

of our readers with little trouble.

Though in a different county, namely, Buckinghamshire, Eton may be faid to be one and the same town with Windfor, for which fee Encycl. It is pleafantly fituated on the banks of the Thames, in a delightful valley, which is of a remarkably healthy foil. Its college was founded by Henry VI. for the support of a provolt and feven fellows, one of whom is vice provolt, and for the education of feventy King's scholars, as those are called, who are on the foundation. These, when properly qualified, are elected, on the first Tuefday in August, to kivg's college Cambridge, but they are not removed till there are vacancies in the college, and then they are called according to feniority; and after they have been three years at Cambridge, they claim a fellowship. Besides those on the foundation, there are feldom less than three hundred scholars, and often many more, who board at the masters houses, or within the bounds of the college. The school is divided into upper and lower, and each of these into three classes. To each school there is a master and four affistants or ushers. The revenue of the college is about L. 5000 a year. Here is a noble library, and in the great court is a fine statue of the founder, erected at the expence of a late provoft Dr Godolphin dean of St Paul's. The chapel is in a good ftyle of Gothic architecture. The schools and other parts, which are in the other flyle of building, are equally well, and feem like the defign of Inigo Jones.

At Eton there is a fingular, and we think a laudable, festival, called the Montem, celebrated triennially (formerly duennially) by the scholars of the school upon Whit-Tuesday. The following account of this sessival, taken from the Monthly Magazine, will probably be

acceptable to many of our readers.

It commences by a number of the senior boys taking post upon the bridges or other leading places of all the avenues around Windsor and Eton soon after the dawn of day. These youths so posted are chiefly the best figures, and the most active of the students; they are all attired in fancy dreffes of filks, fatins, &c. and fome zichly embroidered, principally in the habits or fashion of running footmen, with poles in their hands; they are called falt-bearers, and demand falt, i. e. a contribution from every paffenger, and will take no denial.

When the contribution is given, which is ad lititum,

a printed paper is delivered with their motto and the Bu date of the year, which passes the bearer free through all other falt-bearers for that day, and is as follows, viz.

"Pro more et monte, 1799, (A)

Vivant Rex et Regina." These youths continue thus collecting their falt at all the entrances for near feven miles round Windfor and Eton, from the dawn of day until about the close of the procession, which is generally three o'clock in the afternoon.

The proceffion commences about twelve o'clock at noon, and confifts of the Queen's and other bands of music; several standards borne by different students; all the Etonian boys, two and two, dreffed in officers uniforms; those of the king's foundation wearing blue, the others scarlet uniforms, swords, &c.

The Grand Standard-bearer. The Captain, or Head Boy of Eton School.

The Lientenant, or Second Boy.

His Majesty, attended by the Prince of Wales, and other male branches of the royal family on horseback, with their fuite.

The Queen and Princesses in coaches, attended by

Band of mulic, followed by a great concourse of the Nobility and Gentry in their carriages and on horse-

The procession commences in the great square at Eton, and proceeds through Eton to Slough, and round to Salt Hill, where the boys all pass the king and queen in review, and afcend the Montem: here an oration is delivered, and the grand standard is displayed with much grace and activity by the standard bearer, who is generally felected from among the fenior boys.

There are two extraordinary falt-bearers appointed to attend the king and queen, who are always attired in fanciful habits, in manner of the other falt-bearers already described, but superbly embroidered. falt-bearers carry each an embroidered bag, which not only receives the royal falt, but also whatever is collected by the out-stationed falt-bearers. The donation of the king and queen, or, as it is called upon this occafion, the royal falt, is always fifty guineas each; the Prince of Wales thirty guineas; all the other princes and princesses twenty guineas each. As soon as this ceremony is performed, the royal family return to Windfor. The boys are all fumptuously entertained at the tavern at Salt Hill; and the beautiful gardens at that place are laid out for such ladies and gentlemen as choose to take any refreshments, the different bands of music performing all the time in the gardens.

About fix o'clock in the evening all the boys return in the same order of procession as in the morning (with the exception only of the royal family), and, marching round the great square in Eton school, are dismissed. The captain then pays his respects to the royal family at the queen's lodge, Windfor, previous to his departure for King's College, Cambridge; to defray which expence, the produce of the montem is prefented to him; and upon Whit-Tuesday, in the year 1796, it amounted to more than 1000 guineas. The day con-

cludes by a brilliant display of beauty, rank, and fathion, a promenade on Windfor Terras, bands of music performing, &c. and the scene highly enlivened and enriched by the affable condescension of the royal family, who indifcriminately mix with the company, and parade the Terrace till nearly dark.

SPONTANEOUS EVAPORATION. See WEATHER,

no 17, &cc. Encycl.

EUDIOMETER, an instrument for ascertaining the purity of the atmospherical air. Many have been the contrivances of chemists for this purpose (see Eu-DIOMETER, Encycl.); but perhaps the best eudiometer is that of Morveau (or Guyton, as he now chooses to call himself), of which mention has been made in CHE-MISTRY, no 420. in this Supplement. The following short description will make the nature and use of this

instrument plain to every reader.

AB, (Plate XXVIII.) represents a small glass retort with a long neck; its whole capacity being from feven to nine folid inches. It must be chosen of such a curvature that, when the neck is fet upright, the bulb may form at its lower part a cavity to retain the matters introduced. The extremity of the neck of this retort is ground with emery to enter the glass tube CD, which is open at both ends, and about 12 or 15 inches in length. The retort then closes the tube in the manner of a ground stopper, and intercepts all external communication. A cylindrical glass vessel F is provided, of the form of a common jar, in which the glass tube CD may be entirely plunged beneath the level of the water. Lastly, the sulphuret of potash is prepared and broken into pieces sufficiently small to be introduced into the retort. These are to be inclosed, dry and even hot, in a bottle for use. These constitute the whole apparatus and preparation of materials.

When it is required to examine an aeriform fluid, by separating its oxygen, two or three pieces of the sulphuret, of the fize of a pea, are put into the retort. It is then filled with water, taking care to incline it so that all the air may pass out from the bulb. The orifice of the retort is then to be closed, and inverted into the pneumatic tube, in order that the gas proposed for examination may be transferred into it in the usual manner. By an eafy manœuvre of alternately inclining the retort in different directions, all the water is made to flow out of the bulb in which the fulphuret remains. When this is done, the retort is placed in the vertical fituation, and its extremity introduced into the tube of glass CD, which must always be under water. A small lighted taper is then to be placed under the bulb. 'To support the retort in its position, the jar is provided with a wooden cover, in which there is a notch to receive it.

The first impression of the heat dilates the gaseous fluid fo much that it descends almost to the bottom of the tube, which is disposed expressly for its reception; otherwise the partial escape would prevent an accurate determination of its change of bulk. But as soon as the sulphuret begins to boil, the water quickly rises, not only in the inferior tube, but likewife in the neck of the retort, notwithstanding the application, and even

the increase of the heat.

If the fluid be absolutely pure vital air, the absorption is total. In this case, to prevent the rupture of the veffel by too fudden refrigeration, the afcent of the proportional to the fine of double the distance of the water must be rendered slower, either by removing

the taper, or by increasing the perpendicular height; Endoxie, which will not prevent the absorption from continuing Evection. while any gas remains which is proper to support com-

If the fluid be common air, or oxygen mixed with any other gas, the quantity of water which has entered the retort must be accurately measured after the cooling. It represents the volume of air absorbed. Care must be taken to inclose the remaining gas under the same presfure, by plunging the retort to the level of the line at which the inclosed water rests, before the orifice is stopped.

This operation of measuring, which is very easy when measuring vessels are at hand, may be habitually performed by a flip of paper pasted on the neck of the retort, upon which divisions are drawn from observation, and which must be covered with varnish to defend it

from the action of the water.

EUDOXUS of Gnidus was a celebrated philosopher of the school of Pythagoras. His first preceptor was Archytas, by whom he was instructed in the principles of geometry and philosophy. About the age of twentythree he came to Athens; and though his patrimony was small, by the generous affiltance of Theomedon a physician, he was enabled to attend the schools of the philosophers, particularly that of Plato. The liberality of his friends afterwards supported him during a visit to Egypt, where he was introduced by Agefilaus to king Nectanebis II. and by him to the Egyptian priests. It has been faid that he accompanied Pluto into Egypt; but this is inconfistent with chronology; for Nectanebis II. reigned in Egypt from the second year of the hundred and fourth Olympiad, to the fecond year of the hundred and seventh; and it was before Plato opened his school, that is, before the ninety eighth Olympiad, about the fortieth year of his age, that he vitited Egypt. Eudoxus is highly celebrated by the ancients for his skill in astronomy; but none of his writings on this or any other fubject are extant. Aratus, who has described the celestial phenomena in verse, is said to have followed Eudoxus. He flourished about the ninety-seventh Olympiad, and died in the fifty-third year

of his age. Enfield's Hift of Philosophy.

EVECTION is used by some attronomers for the libration of the moon, being an inequality in her motion, by which, at or near the quadratures, she is not in a line drawn through the centre of the earth to the fun, as she is at the syzygies, or conjunction and opposition, but makes an angle with that line of about 2° 51'. The motion of the moon about her axis only is equable; which rotation is performed exactly in the same time as the revolves about the earth; for which reason it is that the turns always the fame face towards the earth nearly, and would do so exactly, were it not that her monthly motion about the earth, in an elliptic orbit, is not equable; on which account the moon, feen from the earth, appears to librate a little upon her axis, sometimes from east to west, and sometimes from west to east; or some parts in the eastern limb of the moon go backwards and forwards a small space, and some that were conspicuous, are hid, and then appear again.

The term evection is used by some astronomers to denote that equation of the moon's motion which is moon from the fun, diminished by the moon's anoma-

4 L 2

Evenly | Euphon.

ly. This equation is not yet accurately determined; fome flate it at 1° 30', others at 1° 16', &c. It is the greatest of all the moon's equations, except the equation of the centre. Hutton's Distionary.

EVENLY EVEN NUMBER. See NUMBER, Encycl.

EVENLY Odd Number. See NUMBER, Encycl.

EVOLVENT, in the higher geometry, a term used by some writers for the involute or curve resulting from the evolution of a curve, in contradistinction to that evolute, or curve supposed to be opened or evolved. See

EVOLUTE and INVOLUTE, Suppl.

EVOI.UTE, in the higher geometry, a curve first proposed by Huyghens, and fince much studied by mathematicians. It is any curve supposed to be evolved or opened, by having a thread wrapped close upon it, fastened at one end, and beginning to evolve or unwind the thread from the other end, keeping the part evolved or wound off tight stretched; then this end of the thread will describe another curve, called the involve. Or the same involute is described the contrary way, by wrapping the thread upon the evolute, keeping it always stretched. For the Involution and Evolution of Curves, see Involution in this Supplement.

Imperfed Evolute, a name given by M. Reaumur to a new kind of evolute. The mathematicians had hitherto only confidered the perpendiculars let fall from the involute on the convex fide of the evolute: but if other lines not perpendicular be drawn upon the fame points, provided they be all drawn under the fame angle, the effect will fill be the fame; that is, the oblique lines will all interfect in the curve, and by their interfections form the infinitely fmall fides of a new curve, to which they would be fo many tangents. Such a curve is a kind of evolute, and has its radii; but it is an imperfect one, fince the radii are not perpendicular to the first curve or involute.

EUPHON, a musical instrument invented lately by Dr Chladni of Wittenberg, well known by his various publications on philosophical subjects, especially the theory of musical sounds. The cuphon consists of forty-two immoveable parallel cylinders of glass of equal length and thickness; but its construction, tone, and the method of playing it, are totally different from those of the harmonica, with which indeed it has nothing in common but the glass. See HARMONICA, Encycl.

Dr Chladni gives the following account of his inven-In his 19th year he began to learn to play the harpfichord; and he afterwards read a great many of the principal works on the theory of mufic, by which he found that the physico-mathematical part of that science was far more defective than other branches of natural philosophy. Being therefore possessed with an idea that his time could not be better employed than in endeavouring to make discoveries in this department, he accordingly tried various experiments on the vibrations of strings and the different kinds of vibration in cylindric pieces of wood, first discovered, through calculation, by the elder Euler; and found, that though a great deal had been said on the nature of these elastic bodies, yet the manner of vibration and the proportion of tones in other elaftic bodies, which do not proceed, as in the former, in straight lines, but depend on the vibration of whole furfaces, were totally unknown, and that the little which had been written on that subject, by some authors, did not correspond with nature. He had already long remarked, that every plate of glafs or metal emitted various tones according as it was held and struck in different places; and he was desirous to discover the cause of this difference, which no one had ever examined. He sixed in a vice the axle of a brass plate which belonged to a polishing machine, and found, that by drawing the bow of a violin over it, he produced very different tones, which were stronger and of longer duration than those obtained merely by striking it.

'I he observation, that not only strings but also other elastic bodies may be made to produce founds by drawing a violin bow over them, Dr Chladui does not give as a discovery of his own; as the so called iron violin has been long known, and as he had read of an instrument constructed in Italy *, where glass or metal bells * In a were made to found by means of two or more violinb. billibows drawn over them. But the idea of employing Harm this instrument to examine vibrating tones was first energiated by himself. Having accurately remarked the tones produced by the abovementioned metal plate, he found that they gave a progression which corresponded

with the squares of 2, 3, 4, &c.

Not long before he had read, in the Transactions of the Royal Society of Gottingen, the observations of Mr Lichtenberg on the phenomena produced by strewing pounded resin over a glass plate or cake of resin, and he repeated many of his experiments. This led him to the idea that, perhaps, the various vibratory movements of such a plate would be discovered by a diversity of phenomena, if he strewed over it sand or any thing of the like kind. By this experiment there was produced a star-formed sigure; and the author, having continued his researches, published the result of them in a work entitled, Discoveries respecting the Theory of

Sound, printed at Leipsic in 1787.

Whilft he was employed in these investigations, he refolved to invent a new mufical instrument; and he began to confider whether it might not be possible by rubbing glass tubes in a straight line, with the wet fingers, to produce founds, in the same manner as is done in the harmonica by rubbing them circularly. That glass tubes, like those in his euphon, would not merely by fuch rubbing emit any tones, he had long known by theory and experience; and he therefore applied himself to the solution of the difficult question, in what manner the instrument ought to be constructed to anfwer the intended purpole? After various fruitless attempts for a year and a half, during which his imagination was fo full of the idea, that fometimes in his dreams he thought he faw the instrument and heard its tones, that is, like those of the harmonica, but with more distinctuess and less confusion, he at length, in a state between sleeping and waking, obtained a folution of the problem which had given fo much employment to his thoughts. On the second of June 1789, being tired with walking, he fat down on a chair, about nine in the evening, to enjoy a short slumber; but scarcely had he closed his eyes when the image of an instrument, such as he wished for, seemed to present itself before him, and terrified him so much that he awoke as if he had been struck by an electric shock. He immediately started up in a kind of enthusiasm; and made a feries of experiments, which convinced him that what he had feen was perfectly right, and that he had it now in

1 ion. his power to carry his defign into execution. He made his experiments and constructed his first instrument in fo private a manner, that no person knew any thing of them. On the 8th of March 1790 his first instrument of this kind was completed; and in a few days he was able to play on it some easy pieces of music. It was now necessary to give to this instrument, as it was entirely new, a new name; and that of euphon, which fignifies an instrument that has a pleasant found, appeared

to him the most proper.

It was not, however, brought to perfection at once, for he made a fecond inftrument which was an improvement of the first, and a third which was an improvement of the fecond. In found, indeed, and particularly in the higher tones, the first was equal to either of the other two; but the construction was deficient in flrength, fo that every week some hours were necessary to keep it in proper repair; and it was impossible to convey it the distance of a mile without almost totally destroying it. Dr Chladni also, for want of better tubes, employed those used for thermometers, and marked the whole and half tones by a coating of fealing-wax on the under fide; but as the wax, owing to the moiflure and vibration, often cracked and flew off, it was attended with danger to the eyes. It was therefore extremely difficult to give to the construction of the instrument sufficient strength; but this the inventor at length accomplished, so that his new euphon cannot be injured or put out of tune either by playing or by carriage. The third instrument was somewhat different from the first and second; as the fore part, which in the two former rose upwards with an oblique angle, stood at right angles, fo that it could be transported with ease in a particular carriage made for that purpose. Inflead of the thermometer tubes used in the first, the Doctor now employs tubes of different colours. In the second instrument those for the whole tones were of dark green glass; but he used for the half tones, in both, a milk white kind of glass. In a word, the euphon has some resemblance to a small writing desk. When opened, the abovementioned glass tubes, of the thickness of the barrel of a quill and about 16 inches long, are feen in a horizontal position. They are wetted with water, by means of a sponge, and stroked with the wet fingers in the direction of their length, fo that the increase of the tone depends merely on the stronger or weaker pressure, and the slower or quicker movement of the fingers. The number of tubes at present is forty-two. In the back part there is a perpendicular founding-board divided in the middle, through which the tubes pass. It appears therefore that the euphon ought not to be confidered as an altered or improved harmonica, but as a totally new and different inflrument. In regard to sweetness of found, it approaches very near to the harmonica; but it has several advantages which no unprejudiced person, who examines both instruments, will deny.

1. It is simpler, both in regard to its construction and the movement necessary to produce the found, as neither turning nor stamping is required, but merely the movement of the finger. 2. It produces its found speedier; so that as soon as it is touched you may have the tone as full as the inftrument is capable of giving it; whereas, in the harmonica, the tones, particularly the lower ones, must be made to increase gradually.

3. It has more distinctness in quick passages, because Euphons the tones do not refound fo long as in the harmonica, where the found of one low tone is often heard when you wish only to hear the following tone. 4. The unifon is purer than is generally the case in the harmonica, where it is difficult to have perfect glaffes, which in every part give like tones with mathematical exactness. It is however as difficult to be tuned as the harmonica. 5. It does not affect the nerves of the performer; for a person scarcely feels a weak agitation in the singers; whereas in the harmonica, particularly in concords of the lower notes, the agitation extends to the arms, and even through the whole body of the performer. 6. The expence of this instrument will be much less in future than that of the harmonica. 7. When one of the tubes breaks, or any other part is deranged, it can be foon repaired, and at very little expence; whereas, when one of the glaffes of the harmonica breaks, it requires much time, and is very difficult to procure another capable of giving the same tone as the former, and which will correspond sufficiently with the series of the rest.

EUPHORBIA (See Encycl.). Of this plant three new species were discovered by Le Vaillant during his last travels into the interior parts of Africa. The first, which he calls the Cucumber-Euphorbia, adheres to Plate the earth no otherwise than by a few slender roots. It XXVIII. rifes to the height of nine or ten inches only; and ex-fig. 1. actly resembles a cucumber, of which it has the bent shape. It contains abundance of milky juice, which appeared to him as caustic as that of the great euphorbia. Its colour, which is a yellowish green, tinted with a beautiful shade of violet towards the root, gives it a very attractive appearance: but woe betide the man who should be tempted to eat of it! as it is a virulent poison. The fecond, to which he gave the name of the MELON Fig. 20. RIBBED EUPHORBIA, does not rife more than three or four inches from the ground, to which it adheres by a collection of fibrous roots, iffuing from several tubercles disposed in the manner of a crown. The stem forms a flatted globe excavated at the fummit, and has ribs like the apple which in France is called calville blanche. These ribs are elevated, thick, and convex, have a greenish colour, and are marked with brown transversal bands. From the fummit of the ribs iffue feveral little tufts of pedunculate flowers. The third he called the CATERPILLAR-EUPHORBIA, because when he first found Fig 30. it, he thought he perceived on it several beautiful caterpillars. The description of it in a few words is as follows: From a very large tuberous root, which here and there throws out a few thready fibres, iffue feveral stalks almost of the length of the finger: they creep along the ground, are twifted, woody, deltitute of leaves, and furnished with several rows of round tubercles, each guarded by two prickles.

All these kinds of euphorbia are to be dreaded, the last two in particular; because being low and mixed with the herbage like mushrooms, animals, as they feed, run the risk of eating them with their pasture. Our author confirms the account which has been given in the Encyclopadia of the favages poisoning the reservoirs of water with this plant in order to procure the game which shall drink of it. To effect the death of the animal, it is necessary that the poison reach the blood and mingle with it Yet, inconceivable as it may be, the animal, though poisoned, is not the less wholesome

food ..

Entryle food, as our author fays he has experienced. However Exchange, great may be the proportion of euphorbia thrown into a pond of water, he is perfuaded that it never diffuses itself through the whole mass. It is his opinion, that the poison is a refinous juice, which, being from its nature incapable of combining with water, swims on the surface, and there forms a shining greenish oil, which with a little attention may be discerned by the naked eve when the furface is fmooth. I tried (fays he) the qualities of this oil on myself. taking with a straw, from the furface of the basin, a single drop, which I put upon my tongue; and it gave me that kind of burning pain which a caustic occasions. I then took up some water from the refervoir in the hollow of my hand, and blowing off the oily fluid which swam on the surface, I dipped the end of my tongue into the remainder, but could not perceive in it the flightest taste different from that of water itself. He seems to think that milk is an antidote to the poison of euphorbia; because he squeezed fome of the juice into a bason of milk and gave it to an ape, which swallowed part of it without the least injury. He confesses, however, that the dose was trifling

EUSTYLE, is the best manner of placing columns, with regard to their distance; which, according to Vitruvius, should be four modules, or two diameters and

a quarter

EXCENTRIC, or EXCENTRIC CIRCLE, in the ancient Ptolomaic astronomy, was the very orbit of the planet itself, which it was supposed to describe about the earth, and which was conceived excentric with it; called also the deferent.

Instead of these excentric circles round the earth, the moderns make the planets describe elliptic orbits about the fun; which accounts for all the irregularities of their motions, and their various distances from the earth, &c. more juftly and naturally.

EXCENTRIC, or Excentric Circle, in the new astronomy, is the circle described from the centre of the orbit of a planet, with half the greatest axis as a radius; or it is the circle that circumscribes the elliptic orbit of the

EXCHANGE. See Encycl. under that word, and likewise under BILLS of Exchange, where the antiquity of fuch bills, especially among the Chinese, is mentioned. In Professor Beckmann's history of inventions the reader will find an ordinance of the year 1394 concerning the acceptance of bills of exchange, and also copies of two bills of the year 1404, which sufficiently prove that the method of transacting business by bills of exchange was fully established in Europe so early as the fourteenth century; and that the prefent form and terms were even then used. The ordinance, which was issued by the city of Barcelona, decreed that bills of exchange should be accepted within twenty four hours after they were presented, and that the acceptance should be written on the back of the bill.

But there are questions relating to bills of exchange of much greater importance than their antiquity; and these questions are not yet decided. For instance, Ought a bill of exchange to be confidered by the law merely as a deposit telonging to the drawer, and succesfively confided to the remittees? or fhould it be confis Ex dered as transferable property, at all times absolutely vested in the holder, whose neglect therefore, when it Ex

vitiates the value, falls wholly on himfelf?

In a work published 1798 by Professor Busch of Hamburgh, entitled, Additions to the Theoretical and Practical Delineation of Commerce (A), the reader will find fome arguments, which, to fay the least of them, are certainly plaufible, to prove that bills of exchange ought to be at all times confidered as the absolute property of the holder. This theory is then applied to the difficult and still unsettled case of the holder of a bill having many indorfements, where the drawer, drawee, and early indorfers, have all failed. It is evident that, if the holder proves under each bankruptcy the whole amount of the bill, he will receive much more than his due. May he make his election where to prove the whole demand, and where to prove the refidue? Or ought he not (which feems most equitable) to be compelled to prove his debt against his immediate predecessor only?-the assignees of that predecessor proving, in their turn, in like manner (each party once only), back to the drawer. This is a case of great in. portance to discounters, and the reader will find some judicious observations on it in the Professor's work.

EXEGESIS, or EXEGETICA, in algebra, is the finding, either in numbers or lines, the roots of the equation of a problem, according as the problem is either

numeral or geometrical.

EXPECTATION of Life, in the doctrine of life annuities, is the mare, or number of years of life, which a person of a given age may, upon an equality of chance,

expect to enjoy.

By the expectation or share of life, says Mr Simpson (Select Exercises, p. 273), is not here to be understood that particular period which a person hath an equal chance of surviving; this last being a different and more simple consideration. The expectation of a life, to put it in the most familiar light, may be taken as the number of years at which the purchase of an annuity, granted upon it, without discount of money, ought to be valued. Which number of years will differ more or less from the period abovementioned, according to the different degrees of mortality to which the feveral stages of life are incident. Thus it is much more than an equal chance, according to the table of the probability of the duration of life which the same author has given us, that an infant, just come into the world, arrives not to the age of ten years; yet the expectation or share of life due to it, upon an average, is near twenty years. The reason of which wide difference is the great excess of the probability of mortality in the first tender years of life, above that respecting the more mature and stronger ages. Indeed if the numbers that die at every age were to be the same, the two quantities above specified would also be equal; but when the faid numbers become continually less and less, the expectation must of consequence be the greater of the two.

EXPONENTIAL CALCULUS, the method of differencing, or finding the fluxions of exponential quantities, and of fumming up those differences, or finding

their fluents.

EXPONENTIAL

EXPONENTIAL Curve, is that whose nature is defined or expressed by an exponential equation; as the curve denoted by $a^x = y$, or by $x^x = y$.

Exponential Equation, is one in which is contained an exponential quantity: as the equation $a^x = b$, or

EXPONENTIAL Quantity, is that whose power is a variable quantity; as the expression ax, or xx. Exponeutial quantities are of several degrees and orders according to the number of exponents or powers, one over another.

EXTRA CONSTELLARY STARS, fuch as are not

properly included in any conftellation.

EXTRA-MUNDANE SPACE, is the infinite, empty, void space, which is by some supposed to be extended beyond the bounds of the universe, and consequently in which there is really nothing at all. The phrase extramundane space has been so long in use among our best writers, that it is now impossible to banish it from the language; and yet it has been the fource of fome extravagant mistakes. Many philosophers consider space as fomething real, distinct both from body and mind; and no less a man than Dr Clarke considered it as an attribute of the Deity. Yet we think nothing more evident, than that if body had never existed, space would never have been thought of; and if this be fo, extramundane space, instead of denoting any real thing, or attribute infinitely extended, can mean nothing more

than the possibility of enlarging the corporeal universe, Extrados, however widely extended it may be. See METAPHYSICS Extremes. (Encycl.), Part II. ch. iv.

EXTRADOS, the outfide of an arch of a bridge,

vault, &c. See ARCH in this Supplement.

EXTREMES Conjunct, and Extremes Disjunct, in fpherical trigonometry, are, the former the two circular parts that lie next the affumed middle part; and the latter are the two that lie remote from the middle part. These were terms applied by Lord Napier in his univerfal theorem for refolving all right-angled and quadrantal fpherical triangles, and published in his Logarithmorum Canonis Descriptio, an. 1614. In this theorem, Napier condenses into one rule, in two parts, the rules for all the cases of right angled spherical triangles, which had been separately demonstrated by Pitiscus, Lansbergius, Copernicus, Regiomontanus, and others. In this theorem, neglecting the right angle, Napier calls the other five parts circular parts, which are, the two legs about the right angle, and the complements of the other three, viz. of the hypothenuse, and the two oblique angles. Then taking any three of these five parts, one of them will be in the middle between the other two, and thefe two are the extremes conjunct when they are immediately adjacent to that middle part, or they are the extremes disjunct when they are each separated from the middle one by another part.

FACE or FAÇADE, in architecture, is fometimes used for the front or outward part of a building, which immediately presents itself to the eye; or the side where the chief entrance is, or next the street, &c.

FALCONRY is a species of sport, about the antiquity of which there has been some dispute. Under the word HAWKING (Encycl.) we have deduced what we thought fufficient evidence of its being practifed among the Thracians, and likewife among the Britons before the invation of this island by the Romans. Flavius Blondus, however, and Laurentius Valla, both writers of the 15th century, and the latter, one of the most learned men of his time, affirm that no nation or people were accustomed to catch either land or waterfowls with any rapacious bird trained for the purpote.

We were pleased to see our own opinion, so different from this, completely established by the learned labours of Profesior Beckmann. So early (fays he) as the time of Ctesias (and he refers to the page and edition of his author) hares and foxes were hunted in India by means A. Ani. of rapacious birds. The account of Aristotle *, howlib. ix. ever, is still more to the purpose, and more worthy of notice. "In Thrace (fays he) the men go out to catch birds with hawks. The men beat the reeds and bushes which grow in marshy places, in order to raise the small birds, which the hawks pursue and drive to

the ground, where the fowlers kill them with poles." The same account is to be found in another book ascribed also to Aristotle; and which appears, at any rate, to be the work of an author not much younger. Refpecting Thrace, which is fituated above Amphipolis, a wonderful thing is told, which might appear incredible to those who had never heard it before. It is faid that boys go out into the fields, and purfue birds by the affiltance of hawks. When they have found a place convenient for their purpose, they call the hawks by their names, which immediately appear as foon as they hear their voices, and chase the birds into the bushes, where the boys knock them down with sticks and seize them. What is still more wonderful, when these hawks lay hold of any birds themselves, they throw them to the fowlers; but the boys, in return, give them some share of the prey. De mirabilibus auscultat. cap. 128.

In this passage, there are two additions which render the circumstance still more remarkable. The first is, that the falcons appeared when called by their names; and the fecond, that of their own accord they brought to the fowlers whatever they caught themselves. Nothing is here wanting but the spaniel employed to find out game, the hood which is put upon the head of the hawk while it stands on the hand, and the thong used: for holding it, to form a short description of falconry

as still practifed. Our falconers, when they have taken'the bird from the hawk, give him, in return, a small share of it; and in the like manner the Thracian hawks received some part of their booty.

Other writers after Aristotle, such as Antigonus, Ælian, Pliny, and Phile, have also given an account of this method of sowling. Ælian, who seldom relates any thing without some alteration or addition, says that in Thrace nets were used, into which the birds were driven by the hawks; and in this he is followed by the poet Phile. Ælian, also, in another place describes a manner of hunting with hawks in India, which, as we are told by several travellers, is still practised in Persia, where it is well understood, and by other eastern nations.

The Indians (fays he) hunt hares and foxes in the following manner: They do not employ dogs, but eagles, crows, and, above all, kites, which they catch when young, and train for that purpose. They let loose a tame hare or fox, with a piece of sless fastened to it, and suffer these birds to fly after it, in order to seize the sless, which they are fond of, and which, on their return, they receive as the reward of their labour. When thus instructed to pursue their prey, they are sent after wild foxes and hares in the mountains; these they follow in hopes of obtaining their usual food, and soon catch them and bring them back to their masters, as we are informed by Ctesias. Instead of the sless, however, which was fastened to the tame animals, they receive as food the entrails of the wild ones which they have caught.

It feems, therefore, that the Greeks received from India and Thrace the first information respecting the method of fowling with birds of prey; but it does not appear that this practice was introduced among them at a very early period. In Italy, however, it must have been very common, for Martial and Apuleius speak of it as a thing every where known; the former calls a

hawk the fowler's fervant.

The Professor traces the history of this art with great learning down to the present time. It was carried to the highest persection at the principal courts of Europe (he says) in the 12th century, when the ladies kept hawks, which were as much fondled by those who wished to gain their favour as lap-dogs are at present. Among the oldest writers on falconry as an art he reckons Demetrius, who about the year 1270 was physician to the Emperor Michael Paleologus. His book, written in Greek, was first printed at Paris in 1612 with a Latin translation; but its precepts (says our author) would be thought of very little value at present. For an account of the modern art of falconry see Encyclopedia.

FALK (John Peter), known to the world as one of the scientific travellers employed by the late Empress of Rusha to explore her vast dominions, was born in Westrogothia, a province in Sweden, about the year 1727. He studied medicine in the university of Upsal, and went through a course of botany under the celebrated Linnæus, to whose son he was tutor. He publicly defended the differtation (A) which that samous botanist had composed on a new species of plants, which

he called astromeria.

In the year 1760, he was so deeply affected with depression of spirits, that M. de Linné, in the view of obliging him to take exercise and dissipation, sent him to travel over the island of Gothland, to make a collection of the plants it produces, and the various kinds of corals and corallines which the sea leaves on its shores. This voyage was attended with no diminution of his distemper, which found a continual supply of aliment in a fanguine melancholy temperament, in a too sedentary way of life, and in the bad state of his sinances.

Professor Forskael having left Upsal for Copenhagen in 1760, Falk followed him thither, in the design of applying, by the advice of M. de Linné, to be appointed assistant to M. Forskael in his samous journey thro' Arabia; but, notwithstanding all the pains that M. Œ ler, and several other men of literary reputation at Copenhagen, took in his behalf, his application sailed, as the society that were to go on that important expedition was already formed. Obliged, with much discontent, to return, he herborised as he travelled, and enriched the Flora Succiea with several new discoveries.

A man in office at St Petersburgh having written to M. Linné to fend him a director for his cabinet of natural history, M. Falk accepted the post, which led him to the chair of professor of botany at the apothecaries garden at St Petersburgh, a place that had been long vacant. His hypochondriac complaint still continued to torment him. When the Imperial academy of sciences was preparing in 1768 the plan of its learned expeditions, it took M. Falk into its service, though his health was uncertain. He was recalled in 1771; but having got only to Kasan in 1773, he there obtained permission to go and use the baths of Kissiar, from which he returned again to Kasan at the end of

the year, with his health apparently better.

But his difease soon returned with redoubled violence. From the month of December 1773, he had never quitted his bed, nor taken any other nourishment than bread dried in the Swedish manner (knækebræd), of which he scarcely took once a day some mouthfuls dipped in tea. At first he received the visits of a few friends; but afterwards denied himself to them, and was reduced to the firiceft folitude. When M. Geor-gi, member of the fociety of natural history at Berlin, who had been destined to assist and relieve the professor in the duties of his expedition, went to fee him on this occasion, nothing seemed left of him but a skeleton of a wild and terrifying aspect. The few words he drew from him confifted in complaints, occasioned by a liost of difeases which kept his body in torture, and threw him into the most cruel sleeplessness. 'The last evening M. Georgi kept him company till midnight. He fpoke little, and faid nothing that could give reason to sufpect the delign he was meditating. His hunter, and at the same time his trusty servant, offered to sit up with him the night; but he could not be perfuaded to

M. Georgi being requested the next day, March 31, to come to the lodging of the unfortunate gentleman, he found him lying before his bed, covered with blood; beside him lay a razor, with which he had given him-

felf a flight wound in the throat, the fatal pistol, and a powder-horn; all together prefenting a tremendous spectacle. He had put the muzzle of the pistol against his throat, and resting the pommel upon his bed, he difcharged the contents in such a manner, that the ball, having gone through his head, had fluck in the cieling. His foldier had feen him still sitting up in his bed at four o'clock, at which time he usually fell into a short flumber. In his chamber was found a note written the evening before, betraying throughout the distracted state of his mind, but nothing declaratory of his defign,

or that was of any importance.

M. Falk, like all hypochondriac persons, was not very communicative, and on certain occasions was diftrufful. But, at the same time, he was of a sedate temper, complaifant, and upright, which made it a very easy matter to bear with him, and secure to him the indulgence of all his acquaintance. His extreme fobriety had enabled him to make fome favings from his pay, though he was very beneficent; it was not, therefore, indigence that drove him to this act of violence. He was of a cold conflitution, preferring folitude and quiet to fociety, to the company of his friends, and to ordinary amusements, which yet he did not shun, except in the latter period of his life. As to religion, he shewed on all occasions more respect for it than any strong effusions of zeal. It was folely to be ascribed to the violence of his distemper, and the weakness of mind which it brought on, that led him to put a period to his days. The fate of this unfortunate scholar was generally and justly lamented.

His papers were found in the greatest disorder. They contain, however, very useful and important relations. He particularly made it his business to inquire about the Kirguises, and other Tartarian nations; and as he frequently remained for the space of nine months together in the same place, he was enabled to procure satisfactory notions concerning the objects of his investigations. The Imperial academy, in 1774, appointed Professor Laxmann to arrange his manuscripts in order

for publication; which was done accordingly.
FARMER (Richard D. D.), fo well known as one of the commentators on Shakespeare, was a man of such pleafing, though fingular manners, that we regret the very imperfect account which we must give of his life. One of us, who had the pleasure of being a little known to him, has been fo much delighted with the natural case and pleasantry of his conversation, that we made all the inquiries which we judged requifite to enable us to draw up fuch a biographical sketch of this agreeable man as might be acceptable to our readers, and not unworthy of his character; but these inquiries were made in vain. Those to whom we applied knew little more of the incidents of his life than what we had previously found in a miscellany, of which the writers seem to consider it as a principle of duty to vilify the character of every person, who, like Dr Farmer, is the friend of order, and the enemy of fudden or rapid innovations. To that miscellany, therefore, we must be beholden for many facts; but we shall certainly copy none of its malevolence.

Dr Farmer was born at Leicester 1735; but what was the station of his father we have not learned. Of his school education he received part, perhaps the whole, in his native town; and from school he was re-SUPPL. VOL. 1. Part II.

moved to the university of Cambridge, where he devo- Farmer. ted himself chiefly to classical learning and the belles lettres. In 1757, he was admitted to the degree of bachelor of arts; in 1760, to that of master of arts; a bachelor of divinity in 1767, and a doctor of divinity in 1775, in which year he was also elected master of Emanuel on the decease of Dr Richardson, and principal librarian on the decease of Dr Barnardiston.

The disturbances in America having by this time become ferious, the univerfity of Cambridge, with numberless other loyal bodies, voted an address to the king, approving of the measures adopted by government to reduce the factious colonists to their duty. The address, however, was not carried unanimously. It was, of courfe, opposed by JEBB, fo well known for his free opinions in politics and religion, and by fome others, of whom one man, a member of the CAPUT, carried his opposition so far, as actually to refuse the key of the place which contained the feal necessary on such occafions. In this emergency, Dr Farmer, who was then vice-chancellor, is faid to have forced open the door with a fledge-hammer; an exploit which his democratical biographers affect to ridicule, by calling it his courtly zeal, and the occasion of all his subsequent prefer-

If it be indeed true, that he broke the door in pieces with his own hands, his conduct must be acknowledged to have been not very decorous; but if the office which he filled be taken into confideration, we apprehend it would be as difficult to prove that conduct effentially wrong, as to vindicate the obstinate arrogance of him who occasioned it. The seal was the property of the university, of which this outrageous supporter of the bill of rights was but an individual member. The univerfity had refolved that it should be employed for a certain purpose, which it was the duty of the vice-chancellor to carry into effect; and fince the feal was re-fused to him, he had no alternative but to get possesfion of it by force. We hope, however, that he employed a fervant to break the door; and, indeed, as vice chancellor, he must have had so many servants at his command, that it is not conceivable he would wield the fledge hammer himfelf.

Some time after this, he was made a prebendary of Canterbury, we believe through the recommendation of Lord North, then premier; and it was at Canterbury that the writer of this sketch had the happiness of being introduced to him, and witnessing his hospitality. After enjoying his prebend for feveral years, he refigned it on being preferred, by the prefent premier, to a residentiaryship of St Paul's; and we have reason to believe, that he declined a bishopric, which was offered to him as a reward for the constitutional principles which he was at pains to propagate, not only in his college, but, as far as his influence went, through the

whole univertity.

It has been faid, that the delights of the pipe and the bottle in Emanuel parlour outweighed, in his estimation, the dazzling splendor of the mitre; but he had other and better reasons for preferring a private to a public station. In early life, at least before he was advanced in years, he had felt the power of love, and had fuffered fuch a disappointment as funk deep in his mind. and for a time threatened his understanding. From that period, though he retained his faculties entire, he

4 M

acquired some peculiarities of manner; of which he was fo far confcious, as to be fenfible that they would hardly become the character of a bishop: being likewise strongly attached to dramatic entertainments, which, if we mistake not, the English bishops never witness, and delighting in clubs, where he could have rational conversation without state or ceremony of any kind-he very wifely preferred his refidentiaryship to the highest dignity in the church. At the time of his death, which happened in the autumn of 1797, he was a fellow of the Royal and Antiquarian Societies, master of Emanuel college, principal librarian of the public library in the univerfity, one of the canons relidentiary of St Paul's, chancellor of the diocese of Lichfield and Coventry, and prebendary of Worcester.

Though a good claffical fcholar, Dr Farmer has been celebrated only for that kind of literature which is connected with the English drama, and having a strong predeliction for old English writers, he ranked high among the commentators upon Shakespeare. His "Esfay upon the Learning of Shakespeare," dedicated to Mr Cradock, the intelligent resident of Gumley-Hall in Leicestershire, has passed through several editions. This effay was, in fact, the first foundation of his fame, which an unconquerable indolence prevented him from carrying to that height to which the exercise of his literary talents could not have failed to raife it. So great indeed was his love of ease, that after having announced for fubscriptions a history of Leicestershire, and actually begun to print it, rather than submit to the fatigue of carrying it through the prefs, he returned the subscriptions, and prefented the MSS. and plates to Mr Nichols, the respectable printer of the Gentleman's Magazine, who has fince carried on the history with a degree of spirit, ability, and industry, perhaps unprecedented in this department of literature.

Indolence and the love of case were indeed the Doctor's chief characteristics; and to them, with the difappointment already mentioned, may be attributed a want of propriety in his external appearance, and in the usual forms of behaviour belonging to his station. The prevailing features of his character distinguished themselves by several oddities: There were three things, it was faid, which the master of Emanuel loved, viz. old port, old clothes, and old books; and three things which no one could perfuade him to perform, viz. to rife in the morning, to go to bed at night, and to fettle an account. When in Cambridge, if an old house were pulled down, the mafter of Emanuel was always there in an old blue great coat, and a rufty hat. When in London, he was fure to be found in the same garb at an old book stall, or standing at the corner of a dirty lane, poring through his glass at an old play bill.

This character is not drawn by a friendly pencil; but it is nevertheless not unjust. His inattention to the common decencies of dress and behaviour was notorious, infomuch that, in the company of strangers, the eccentricity of his appearance and of his manners made him fometimes be taken for a person half crazed. 'The writer of this sketch saw him one morning at Canterbury dreffed in flockings of unbleached thread, brown breeches, and a wig not worth a shilling; and when a brother prebendary of his, remarkable for elegance of manners, and propriety of drefs, put him in mind that they were to attend on the archbishop, Dr Farmer re-

plied, that it had totally escaped him; but he went Farm home, and dreffed himself like a clergyman. That he Fasti fat late reading, and occasionally drinking brandy and, water, cannot be denied; and it is literally true, that he could not easily be prevailed upon to settle his accounts. His accounts with fome of his pupils, when tutor of his college, were never fettled to the day of his death; and the young gentlemen not unfrequently took advantage of this unconquerable indolence to borrow of him confiderable fums, well knowing that there was little chance of a demand being ever made upon their pa-One gentleman, in particular, told a friend of ours, who was himself a pensioner of Emanuel, that when he left that college, he was near fifty pounds in debt to Dr Farmer; "a debt (faid he) which I would have ferupuloufly paid, but, after repeated folicitations.

I could get no bill from him."

Having been a warm partizan of government during the American war, it will readily be believed that Dr Farmer was the determined enemy of levellers and anarchists. He was fuch a Whig as those who placed King William on the throne; and of course deemed a violent Tory by our prefent republicans, of whom, to fay the truth, he could hardly speak with temper. By his enemies he is admitted to have been a man of generosity. As he obtained money easily, so he parted with it easily. Whilst he was always ready to relieve distress, his bounty was frequently bestowed on the patronage of learned men and learned publications. He was, accordingly, a favourite with all good men who knew him. In his own college he was adored; in the university he had, for many years, more influence than any other individual; and, with all his eccentricities, his death was a loss to that learned body, which, in the opinion of some of its members, will not soon be made

FASCINATION, the art of bewitching, enchantment, an unseen inexplicable influence. title SERPENS (Encycl. n° 22.) we have mentioned feveral inflances of the fascinating power of the rattlefnake, which were related by men of character, and certainly gained some degree of credit among men of science. In Vaillant's New Travels into the Interior Parts of Africa, an account is given of fimilar inflances of fascination by African servants, some of them witneffed by himfelf, and others reported to him by men

of veracity

On the confines of the European colony, at a place called Swart-land, our traveller faw a shrike on the branch of a tree, tremble as if in convulsions, whilst it uttered the most piercing cries of distress. Closer attention led him to discover upon the next branch of the same tree a large serpent, that, with stretched-out neck, and fiery eyes, though perfectly Itill, was gazing on the poor animal. He shot the serpent; but, in the mean time, the bird had died. Having measured the distance between the place where the shrike was seen in convulsions and that occupied by the serpent when it was shot, he found it to be three feet and a half; which convinced him and his attendants that the bird had not died either from the bite or the poison of its enemy. Indeed he stripped it before the whole company, and made them observe that it was untouched, and had not received the flightest wound .- In another district of Africa, during the course of the same travels, he na- faw a small mouse die in convulsions, occasioned by the fascinating power of a serpent, at the distance of two yards from it; and when he confulted his Hottentots upon this incident, they expressed, he says, no fort of altonishment, but affured him that the serpent had the faculty of attracting and fascinating such animals as it wished to devour.

We have already had occasion to remark how regardless this author is of inconfiftencies in his narrative; and we perceive fomething like an inconfiftency in the narratives before us. Though his Hottentots expressed no surprise at the fascination of the mouse, and declared that nothing was more common, he fays expressly, that to those who witnessed the fascination of the shrike, the fact appeared so extraordinary, that they could hardly believe it, even after they had feen it.

The most wonderful instance of fascination which we have anywhere met with, was that of a Captain in the Dutch fervice at the Cape, who, after affuring our traveller that it is an event which happens very frequently, proceeded thus: "My testimony ought to have the more weight, as I had once nearly become myfelf a victim to this fascination. While in garrison at Ceylon, and amufing myfelf, like you, in hunting in a marsh, I was, in the course of my sport, suddenly seized with a convulfive and involuntary trembling, different from any thing I had ever experienced, and at the fame time was ftrongly attracted, and in spite of myself, to a particular fpot of the marsh. Directing my eyes to this spot, I beheld, with feelings of horror, a ferpent of an enormous fize, whose look instantly pierced me. Having, however, not yet loft all power of motion, I embraced the opportunity before it was too late, and faluted the reptile with the contents of my fusee. The report was a talisman that broke the charm. All at once, as if by a miracle, my convulsion ceased; I felt myfelf able to fly; and the only inconvenience of this extraordinary adventure was a cold fweat, which was doubtless the effect of my fear, and of the violent agitation my fenfes had undergone."

This inftance of fascination differs in one very material circumstance from the two somewhat similar instances mentioned in the Encyclopadia. In both thefe, the eyes of the perfons fascinated were fixed on the eyes of the fnake; but here the Dutch Captain was strongly attracted towards the serpent before he saw, or even suspected that so formidable an enemy was in his neighbourhood. If the story therefore be true, the effect which he describes could not possibly have been the effect of fear, but of some unseen influence on his

whole nervous fystem.

The subject has of late attracted the attention of men of science, whose local situation gives them an opportunity of making experiments upon different ferpents, with a view to afcertain whether they really poffess or not this most unaccountable of all powers. the year 1796 was printed at Philadelphia a Memoir concerning the Fascinating Faculty which has been ascribed to the Rattle-snake, and other American Serpents, by Benjamin Smith Barton, M. D. Professor of natural history and botany in the university of Pennsylvania In this memoir, the manner in which the fascinating power is supposed to be exerted is thus stated by the ingenious professor:

"The fnake, whatever its species may be, lying at Fascinathe bottom of the tree or bush upon which the bird or squirrel fits, fixes its eyes upon the animal it defigns to fascinate or enchant. No sooner is this done, than the unhappy animal is unable to make its escape. It now begins to utter a most piteous cry, which is well known by those who hear it, and understand the whole machinery of the business, to be the cry of a creature enchanted. If it is a squirrel, it runs up the tree for a short diffance, comes down again, then runs up, and, lastly, comes lower down. 'On that occasion (fays an honest, but rather credulous writer *), it has been observed, that * Professor

the fquirrel always goes down more than it goes up.' Peter Kalm's The fnake still continues at the root of the tree, with its eyes fixed on the squirrel, with which its attention is fo entirely taken up, that a person accidentally approaching, may make a confiderable noise without the fnake's fo much as turning about. The fquirrel, as before mentioned, comes always lower, and at last leaps down to the fnake, whose mouth is already wide open for its reception. The poor little animal then, with a piteous cry, runs into the fnake's jaws, and is fwallowed at once, if it be not too big; but if its fize will not allow it to be fwallowed at once, the fnake licks it feveral times with its tongue, and fmoothens it, and by

that means makes it fit for fwallowing."

From Dr Barton's memoir, it appears that the North American Indians are by no means of one opinion refpecting the fascinating power of the rattle-snake. Some intelligent friends of his, well acquainted with the manners, religious opinions, and superttitious prejudices of those people, informed him, that though they had often heard the Indians speak of the ingenuity of these reptiles in catching birds, fquirrels, &c. they did not recollect having ever heard them fay that fnakes charm birds. On the other hand, however, a Mohegan Indian told the Doctor himfelf, that the Indians are of opinion, that the rattle make can charm, or bewitch, squirrels and birds, and that it does this with its rattle, which it shakes, thereby inviting the animals to descend from the trees, after which they are eafily caught. According to this Indian, his countrymen do not think that the fnake, in any manner, accomplishes the business with its eyes. A Choktah Indian affured the Doctor, that the rattle-fnake does charm birds, &c.; but he was honest enough to confess, that he did not know in what manner it does it. The interpreter, through whom the conversation was carried on with this Indian, faid that the fnake charms by means of its rattle.

This opinion of the interpreter was the opinion of That eminent naturalist, controverting, about fifty years ago, the common opinion, that Providence has furnished the rattle-snake with its rattle to give warning to travellers, was the full who afferted that this fingular appendage is given to the animal to terrify squirrels and small birds, which are then so stupified by the fight of fo formidable an enemy, that at length they drop down, and become its prey; and that this is what the Indians call fascination. The same opinion has been adopted by professor Blumenbach of Gottingen, who, in his Manual of Natural History, thus expresses himself on this curious subject:

"That squirrels, small birds, &c. fall down spontaneoully from trees into the mouth of the rattle-fnake,

Fascina- lying below them, is an undisputed fact; and is the tends, under certain circumstances, to a considerable Fascin less surprising, as the like phenomena have been remarked in regard to other fnakes, and also toads, hawks, and cats; all of which, in certain circumstances, as appears, have the power of drawing towards them small animals, merely by fixing their eyes stedfastly on them. In regard to the rattle fnake, this effect is produced by the rattle in its tail, the hiffing noise of which makes fquirrels, &c. whether through curiofity, mistake, or terror, feem to approach the animal as it were fpontaneoully. At any rate, I know, from the information of intelligent eye-witnesses, that it is a common stratagem of the young favages in America to conceal themfelves in the bushes, where they imitate the hissing noise of the rattle-fnake, and by these means attract squirrels; which they are then enabled to catch."

To this opinion Dr Barton opposes an insuperable objection. It is, that this fascinating power is by no means peculiar to the rattle-snake. With regard to the stratagem of the savages, he thinks that Dr Blumenbach has been imposed upon; as neither he, nor any other person of whom he made the inquiry, ever heard of fuch a stratagem. The young Indians, he fays, place a reed cross-wise in their mouth, and by a tremulous motion of the lips, imitate the cry of young birds; by which means they entice the old ones, so that they can casily shoot them: And this practice may have given rife to the story of their imitating the hissing

noise of the rattle-snake.

Some have supposed that serpents, under certain circumstances, emit from their bodies a stupifying vapour; and that it is this vapour which produces the effect called fascination: But against this opinion Dr Barton alleges the following arguments: "I know, indeed (fays he), that in some of the larger species of serpents, inhabiting South America and other countries, there is evolved in the stomach, during the long and tedious situation was not uneasy. process of digestion in these animals, a vapour or a gas, whose odour is intenfely fetid. I have not, however, found that this is the cafe with the rattle fnake, of not a little attention to the subject has taught me, and other North American ferpents, that I have exa- that there is but one wonder in the butiness;—the wonmined. But my own observations on this head have der that the story should ever have been believed by a not been very minute. I have made inquiry of some perfons (whose prejudices against the serpent tribe are not fo powerful as my own), who are not afraid to put the heads and necks of the black fnake, and other ferpents that are destitute of venomous fangs, into their mouths, and have been informed, that they never perceived any difagreeable fmell to proceed from the breath of thefe animals. I have been present at the opening of a box which contained a number of living ferpents, and although the box had been fo close as to admit but a very small quantity of fresh air, although the observation was made in a small warm room, I did not perceive any peculiarly difagreeable effluvium to arife from the bodies of these animals. I am, moreover, informed by a member of this fociety *, who has, for a confi-Philosophi- derable time, had a rattle-snake under his immediate cal Society. care, that he has not observed that any disagreeable vapour proceeds from this reptile. On the other hand, however, it is afferted by some creditable persons of my acquaintance, that a most offensive odour, similar to that of flesh in the last stage of putrefaction, is continually emanating from every part of the rattle fnake, and some other species of serpents. This odour ex-

distance from the body of the animal. Mr William Bartram affures me, that he has observed 'horses to be fensible of, and greatly agitated by it, at the distance of forty or fifty yards from the snake. They shewed (he fays) their abhorrence by fnorting, winnowing, and flarting from the road, endeavouring to throw their riders, in order to make their escape.' This fact, related by a man of rigid veracity, is extremely curious; and, in an especial manner, deserves the attention of those writers who imagine that this fetid emanation from ferpents is capable of affecting birds, at small distances, with a kind of asphyxy. It even gives some colour of probability to the story related by Metrodorus, and preferved in the Natural History of Pliny 1.

Some experiments, however, which were made in Cap. 14. Philadelphia a little before the Doctor composed his memoir, feem to have been decifive not only as to the fetor, but as to every thing which refembles fascination in the rattle-fnake. Birds which were put into a cage which contained a rattle-fnake, flew or ran from the reptile, as though they were fensible of the danger to which they were exposed. The fnake made many attempts to catch the birds, but could feldom fucceed. When a dead bird was thrown into the cage, the fnake devoured it immediately. He foon caught and devoured a living mole, an animal much more fluggish than Dr Barton himself faw a snow-bird (see Emthe bird. BERIZE Encycl.) in a cage with a large rattle-fnake. The little animal had been thus imprisoned for several hours when he first faw it, but it exhibited no figns of fear. It hopped about from the floor of the cage to its rooft, and frequently perched on the snake's back. Its chirp was nowife tremulous, but perfectly natural. It ate the feeds which were put into the cage; and by its whole actions most evidently demonstrated that its

Having thus disposed of the doctrines of some of his predecessors, Dr Barton proceeds to fay: "The result man of understanding and of observation." Fascination, we are informed, is almost entirely limited to birds that build low, and " in almost every instance, I found that the supposed fascinating faculty of the serpent was exerted upon the birds at the particular season of their laying their eggs, of their hatching, or of their rearing their young, still tender and defenceless. I now began to suspect, that the cries and fears of birds supposed to be fascinated originated in an endeavour to protect their nest or young. My inquiries have convinced me that this is the case."

The rattle-snake, which is the laziest of all the serpent tribe, never moves in a spiral manner or climbs up trees; but the black fnake, and fome other species of the genus coluber, do. When impelled by hunger, and incapable of fatisfying it by the capture of animals on the ground, they begin to glide up trees or bushes upon which a bird has its nest. The bird is not ignorant of the ferpent's object. She leaves her nest, whether it contains eggs or young ones, and endeavours to oppose the reptile's progress. In doing this, she is actuated by the strength of her instinctive attachment to her eggs, or of affection to her young. Her cry is melancholy, her

imminent danger. Sometimes she approaches so near It go the reptile that he seizes her as his prey. But this is far from being univerfally the case. Often she compels the ferpent to leave the tree, and then returns to her

It is a well-known fact, that among some species of birds, the female, at a certain period, is accustomed to compel the young ones to leave the nest; that is, when the young have acquired fo much firength that they are no longer entitled to all her care. But they still claim some of her care. Their flights are aukward, and foon broken by fatigue. They fall to the ground, where they are frequently exposed to the attacks of the ferpent, which attempts to devour them. In this situation of affairs, the mother will place herself upon a branch of a tree or bush, in the vicinity of the serpent. She will dart upon the ferpent, in order to prevent the deftruction of her young: but fear, the instinct of self-preservation, will compel her to retire. She leaves the ferpent, however, but for a short time, and then returns again. Oftentimes she prevents the destruction of her young, attacking the fnake with her wings, her beak, or her claws Should the reptile fucceed in capturing the young, the mother is exposed to less danger. For, whilst engaged in swallowing them, he has neither inclination nor power to feize upon the old one. But the appetite of the serpent-tribe is great: the capacity of their stomachs is not less so. The danger of the mother is at hand when the young are devoured. The fnake feizes upon her: and this is the catastrophe, which crowns the tale of fascination!

FAUSSE BRAYE, in fortification, an elevation of earth, about three feet above the level ground, round the foot of the rampart on the outside, defended by a parapet about four or five fathoms distant from the upper parapet, which parts it from the berme and the The fausse-braye is the same with edge of the ditch. what is otherwise called Chemin des rondes, and Baffe enceinte; and its use is for the defence of the ditch.

FEATHER-EDGED, is a term used by workmen for fuch boards as are thicker on one edge, or fide, than on the other.

FEL'TING, the method of working up wool or hair into a kind of cloth or stuff, without either spinning or weaving it. In this country felting is little practifed except in hat-making; and as nine tenths of those who are employed in the manufacturing of hats know nothing of the principles on which they proceed, the following observations on the mechanism of felting must to them be both agreeable and useful. They are by M. Monge, and taken from the Annales de Chemie.

If we examine, in a microscope, human hair, wool, the hair of a rabbit, hare, beaver, &c. however great the magnifying power of the instrument may be, the furface of each hair appears perfectly smooth and even; or at least, if any inequalities are to be perceived, they seem rather to arise from some difference in the colour and transparency of particular parts of these substances than from the irregularity of their furfaces; for their image, when viewed by a folar microscope, is terminated by even lines, without any roughness. The furface of these objects, however, is by no means smooth; on the contrary, it appears to be formed either of lamella which cover each other from the root to the

motions are tremulous. She exposes herself to the most point, pretty much in the same manner as the scales of Felting, a fish cover the animal from the head to the tail; or, more probably, of zones placed one over the other, like what is observed in the structure of horns: to this conformation it is, that the substances here treated of owe their disposition to what is called felting.

If, with one hand, we take hold of a hair by the root, and draw it between two fingers of the other, from the root towards the point, we are hardly fensible of any friction or relitance, nor can we diftinguish any found; but if, on the contrary, we hold the hair at the point, and draw it between the singers, from the point towards the root, we are fensible of a resistance which did not exist in the former case; a sort of tremulous motion is likewife produced, which is not only perceptible to the touch, but may also be distinguished by

It is evident therefore, that the texture of the furface of a hair is not the same from the root towards the point as from the point towards the root; and that a hair, when grasped, must offer more resistance in sliding or moving progressively towards the point than towards the root; i. e. in moving with its point foremost.

If a hair, after being taken hold of by the fore finger and thumb, be rubbed by them, in the longitudinal. direction of the hair, a progressive motion takes place, and this motion is always towards the root. This effect does not at all depend on the nature of the skin of the fingers or its texture; for if the hair be turned, fo that the point is placed where the root was, the movement. then becomes contrary to what it was before; that is to

fay, it is always directed towards the root. What is observed, in the above instance, is entirely analogous to what happens when country children, by way of sport, introduce an ear of rye or barley between. the wrist and the shirt, the points of the beards of which are directed outwards. By the various motions of the arm, this ear, fometimes catching against the shirt, fometimes against the skin, takes a progressive motion backwards, and foon gets up to the arm-pit. It is very clear that this effect is produced by the beards of the ear, and indeed chiefly by the asperities upon those beards; which, being all directed towards the point, do not permit the ear to move in any other direction. than towards that part to which it was united to the stalk. There is no doubt that it is the same with respect to hair; and that its surface is beset with asperities, which, being laid one upon the other, and turned towards the points, permit no motion but towards the

A tight knot, made in the middle of a hair, is very difficult to untie by the usual means, on account of the extreme thinnels of the hair; but if we place the hair in the bend of the hand, so that the knot is in a line. with the little finger, and, after grasping the hair by closing the hand, we strike the fift several times against the knee, the asperities of one end of the hair being now in a contrary direction to those of the other, each of the ends recedes a little, one of them one way, the other the contrary way; the knot is thereby opened, and, by introducing a pin into the eye which is formed, it is very eafy to finish untying it.

These observations, which it would be useless to multiply, relate to long hair, that having been taken as an example; but they apply with equal propriety to wool,

furface of all these is therefore to be considered as composted of hard lamella placed one upon another, like tiles, from the root to the point; which lamella allow the progressive motion of the hair towards the root, but

prevent a fimilar motion towards the point.

From what has been faid, it is eafy to explain why the contact of woollen stuffs is rough to the skin, while that of linen or cotton cloths is smooth; the reason is, the afperities upon the furface of the fibres of the wool (notwithstanding the flexibility of each particular fibre), by fixing themselves in the skin, produce a disagreeable fenfation, at least till we are accustomed to it; whereas the furface of the fibres of hemp or flax, of which linen is made, being perfectly smooth, do not cause any fuch fenfation. It is also evident, that the injury arising to wounds or fores, from the application of wool, does not proceed from any chemical property, but is occasioned folely by the conformation of the furface of the fibres; the asperities of which attach themselves to the raw and exposed flesh, which they stimulate and irritate to If fuch a degree as to produce inflammation.

This conformation is the principal cause of that difpolition to what is called felting, which the hair of all

animals in general possesses.

The hatter, by striking the wool with the string of his bow (fee HAT, Encycl.), separates the hairs from each other, and causes them to spring up in the air; the hairs fall again on the table, in all possible directions, fo as to form a layer of a certain thickness, and the workman covers them with a cloth, which he preffes with his hands, moving them backwards and forwards in various directions. This preffure brings the hairs against each other, and multiplies their points of contact; the agitation of them gives to each hair a progreffive motion towards the root; by means of this motion the hairs are twisted together, and the lamella of seach hair, by fixing themselves to those of other hairs which happen to be directed the contrary way, keep the whole in that compact flate which the preffure makes it acquire. In proportion as the mass becomes compact, the pressure of the hands should be increased; not only to make it more close, but also to keep up the progressive motion and twisting of the hairs, which then takes place with greater difficulty: but throughout the whole of this operation, the hairs fix themselves only to each other, and not to the cloth with which they are covered, the fibres of which, as we have already faid, are smooth, and have not that disposition to felt-, ing which we have described above.

It may not be amis here to explain why that hair which is intended for making hats is always cut off - with a tharp instrument (although that cannot be done without losing a part of its length), and not plucked out by the roots, as might be done after foftening the skin: the reason is, the bulb of the hair, which in the latter case would come out with it, would render that end which was fixed in the skin thick and obtuse; and it would confequently be left disposed to introduce itself among the contiguous hairs, and to contribute by its progressive motion to the contexture of the mass.

The above described conformation of the surface of hairs and wool is not the only cause which produces their disposition to selting. It is not sufficient that every hair possesses the forementioned tendency to move

Felsing furs, and in general to every kind of animal hair. The progressively towards the root, and that the inclined la- Felsing mella, by hooking themselves to each other, preserve the dergul mass in that state to which compression has brought it; but it is also necessary that the hairs should not be straight, like needles; if they were fo, pressing and rubbing them together would merely cause them to continue their progressive motion, without changing their direction; and the effect of those operations would only be to make them move from the centre of the mais, without producing any compactness in it. Every hair must therefore be twisted or curled in fuch a manner that the extremity which is towards the root may be disposed to change its direction perpetually, to twilt itself about other hairs, and to incline towards itself again, in case it should be determined thereto by any change in the position of the rest of its length. It is because wool has naturally this crooked form that it is fo proper for felting, and that it may be made use of for that purpose without undergoing any previous preparation.

But the hairs of the beaver, the rabbit the harc, &c. being naturally straight, cannot be employed alone in felting till they have undergone a preliminary operation; which confitts in rubbing or combing them, before they are taken off the skin, with a brush dipped in a solution of mercury in aquafortis (nitric acid). This liquor, acting only on one fide of the fubstance of the hairs, changes their direction from a right line, and gives them that disposition to felting which wool naturally

possesses.

When the hairs are not intended to enter into the body of the mass, but are only to be employed in making a fort of external coating, fuch as is fometimes given to the outer furface of hats, the operation just mentioned need not be performed; but the felt on which they are to be fixed being finished, the hair is uniformly spread upon the furface to which the coating is to be applied; and, being covered with a cloth, it is pressed with the hands, and agitated for a certain time. By these means, the hairs introduce themselves, by the root, a certain depth into the felt, and are there fixed by their lamellæ in fuch a manner as not to be easily extracted. A particular direction is afterwards given to them by means of a brush, and they are made to keep this direction by having a hot iron passed over them. If the agitation were continued for a longer time, these hairs, not having their straightness destroyed by the operation before described, would pass entirely through the felt, going out at the opposite surface, as each hair follows exactly the direction it acquired at the be-

It is owing to the very fame circumstances which make wool and hair capable of felting, that woollen cloth is thickened by fulling. See Fulling in this

Supplement.

FERGUSSON (Robert), who at an early period of life obtained a confiderable degree of celebrity as a Scottish poet, was born at Edinburgh on the 5th of September 1750, according to a manufcript account of him with which we have been favoured by a relation. In the biographical sketch prefixed to the Perth edition of his poems he is faid to have been born in 1751.

His father William Fergusson possessed, as well as himself, some talents for poetry; but, marrying early, and being wifer than his fon, he abandoned the mufes

fer on for trade, and was employed in different mercantile houses, first in Aberdeen and afterwards in Edinburgh. At the time of his death he was an accountant in the British linen hall; but never acquired any thing like

During the years of infancy and childhood, the conflitution of our poet was fo weak, that little hopes were entertained of his arriving at manhood. By the care, however, and attention of his parents, he gradually acquired firength, and at the age of fix was put to an English school, where his proficiency in reading and reciting was uncommonly great. At the age of feven he was fent to the high school of Edinburgh, where he continued four years, and with very little labour made a rapid progress in the knowledge of the Latin tongue; but for fome reason or other he was removed from the high school to the grammar school of Dundee, whence, after two years, he was fent to the university of St Andrews. A gentleman of the name of Fergusson had left burfaries in that university for the education of two boys of the fame name; and Mr William Fergusson having with difficulty obtained one of them for his fon, was induced to educate him at St Andrews in preference to Edin-

Though at no period of his life a fevere student, our poet's attainments in science were such as to keep alive in the univerfity the hopes which had been formed of him at school; and he was confessedly the first mathematician of his standing. On this account we are told that he became the favourite of Dr Wilkie, who was then professor of natural philosophy in the university of St Andrews; but it is not improbable that the Doctor valued him as much for his poetical genius as for his skill in geometry; for Wilkie was a poet himself, and Mr Fergusson had already written several small poems which attracted confiderable notice, as well from the professors as from his fellow-students. But whatever was the bond of union, Dr Wilkie patronifed the youthful poet; and the poet shewed afterwards that he was not ungrateful. Upon the Doctor's death, he published, in the Scottish dialect, a beautiful ecloque to his memory, in which the peculiar merits of that eccentric genius are appreciated with great judgment. WILKIE, in this Supplement.

During the last winter that he resided in St Andrews, our poet had collected materials for a tragedy on the death of Sir William Wallace, and had even completed two acts of the play; but having feen a fimilar work on the same subsect, he abandoned his defign; "because (said he to a friend) whatever I publish shall be original, and this tragedy might be consi-

dered as a copy."

Having finished his studies at the university, he returned to Edinburgh without refolving on any permanent employment. His father had defigned him for the church; but he was now dead, and our author turned a deaf ear to the intreaties of his mother, and of every other friend who endeavoured to perfuade him to fulfil his father's intention. He was then advised to fludy physic; but he declined it, because, he said, that, when reading the description of diseases, he fancied that he felt the fymptoms of them all in himself. To the law, however, he could not flart the fame objection; and he began to study it, but made no progress. At this his relation and the editor of his poems express no

furprife; for, according to them, it was a study the Ferguston. most improper for him, as it could not be expected that a genius fo lively would fubmit to the drudgery of that

dry and fedentary profession.

That the law was a very improper profession for a man of his narrow fortune is indeed true; but we trust that his two biographers will not confider us as intending any offence to them, if we embrace the present opportunity of exposing the folly of a very common remark, that a lively genius cannot submit to what is abfurdly called a dry fludy. We might instance different lawyers at our own bar, who, with great poetical talents in their youth, have rifen to the fummit of their pfofession; but to avoid personal distinctions at home, we shall take our examples from England. The genius of the late Earl of Mansfield was at least as lively as that of Mr Fergusson, and if he had pleased he could have been equally a poet; yet he submitted to the drudgery of studying a law still drier than that of Scotland. To the fine tafte of Atterbury bishop of Rochefter, and to his claffical compositions both in profe and verse, no man is a stranger who is at all conversant in English literature: yet that elegant scholar and poet, after he had risen to the dignity of Dean of Carlisle, submitted to the drudgery of studying, through the medium of barbarous Latin, the eccletiastical law of England from the earliest ages; and declated, that by dint of perseverance he came in time to relish it as much as the study of Homer and Virgil. Whatever be thought of Milton's political principles, no man can read his controverfial writings, and entertain a doubt but that he could have submitted to the drudgery of studying the law.

The truth is, and it is a truth of great importance, that a man of real vigour of mind may bring himself to delight in any kind of fludy which is useful and honourable. Such men were Lord Mansfield, the Bishop of Rochester, and Milton; but, whether through some radical defect in his nervous fystem, or in consequence of early diffipation, Mr Fergusson, with many estimable qualities, was fo utterly destitute of this mental vigour, that rather than submit to what his friends call drudgery, he feems to have looked with a wishful eye to

fome finecure place.

With this view he paid a vifit to an uncle who lived near Aberdeen, a man of great learning and in opulent circumstances, in hopes that, by his interest, he might be fettled in a post suitable to his merit: But how delusive were his hopes! His uncle indeed received him with every mark of affection; but his fondness gradually cooled, and at the end of fix months, he ordered him abruptly to leave his house, without having endeavoured

to procure for him any fettlement.

To a mind like Fergusson's, feelingly alive, fuch treatment from fo near a relation, to whom he had always behaved with becoming respect, must have been dreadfully galling. Stung with indignation, he returned to his mother's at Edinburgh; and as foon as he recovered from a severe illness, brought upon him by disappointment and the fatigue of his journey, he compoled two elegies; one on "The Decay of Friendship," and the other " Against Repining at Fortune," both occasioned by his adventure in the North. How much he felt the dashing of his hopes, is apparent from the following pathetic lines in the Decay of Friendship:

But, ah! these youthful sportive hours are sled,
These scenes of jocund mirth are now no more;
No healing slumbers 'tend my humble bed,
No friends condole the forrows of the poor.

And what avail the thoughts of former joy?

What comfort bring they in the adverse hour?

Can they the canker-worm of care destroy,

Or brighten fortune's discontented lour?

So destitute was he at this period, that he submitted to copy papers in the commissary clerk's office, we believe at so much the sheet; but not liking the employment, and quarrelling with the commissary clerk-depute,

he foon left the office in difgust.

Hitherto he had lived rather in o'ofcurity; and happy had it been for him, if in that obscurity he had been fuffered to remain: happy had it been for him, had his conversation been less fascinating, and his company less courted by the frolic and the gay. Possessing an inexhaustible fund of wit, the best good nature, much modesty, and great goodness of heart, he was viewed with affection by all to whom he was known; but his powers of fong, and almost unrivalled talents for mimickry, led him oftener into the company of those who wished for him merely to enliven a focial hour, than of fuch as by their virtue were inclined, and by their influence were able, to procure him a competent fettlement for life. The consequence of this was great laxity of manners. His moral principles indeed were never corrupted, nor, as we have reason to believe, his faith in revelation shaken; but there is no doubt but that, courted as he was by the fyren voice of pleafure, he yielded to many temptations, and in the hours of ebriety committed actions which, in his cooler moments, he reflected on with abhorrence.

His conscience was indeed frequently roused. Being on a visit to a friend at Haddington, and sauntering one day near the church yard, he was accossed by a clergyman, who seemed to be no stranger to the kind of life which he led. This judicious divine contrived to draw his attention to the shortness of time, the length of eternity, death and judgment, and the awful state that awaits the wicked in an unseen world; and the conversation made a deep impression on his mind. It seemed, however, to be essayed from his memory by the dissipation of Edinburgh, till it was recalled with double effect

by the following accident:

In the room adjoining to that in which he flept was a starling, which being seized one night by a cat that had found its way down the chimney, awaked Mr Fergussion by the most alarming screams. Having learned the cause of the alarm, he began seriously to reslect how often he, an immortal and accountable being, had in the hour of intemperance fet death at defiance, though it was thus terrible in reality even to an unaccountable and finless creature. This brought to his recollection the conversation of the clergyman, which, aided by the folemnity of midnight, wrought his mind up to a pitch of remorfe that almost bordered on frantic despair. Sleep now forfook his eyelids; and he rose in the morning, not as he had formerly done, to mix again with the focial and the gay, but to be a recluse from fociety, and to allow the remembrance of his past follies to prey upon his vitals. All his vivacity now forfook him; those lips which were formed to give delight, were clofed as by the hand of death; and "on his countenance Fergula fat horror plum'd."

From this state of glocmy despondency, however, he began gradually to recover; and, except that a settled melancholy was visible in his countenance, his health was completely restored, when one evening he sell and cut his head so dreadfully, that from the loss of blood he became delirious. In this deplorable state he continued for several months, till, being quite exhausted by want of sleep and constant speaking, he expired on the 16th of October 1774. He was interred in the Canongate church-yard, where his friends erected a monument to his memory, which has been since removed to make way for a larger and more elegant monument by his enthusiastic admirer the late poet Burns.

Thus died Robert Fergusson, a young man of the brightest genius and of the best heart, who, had he joined prudence to his uncommon talents, must have risen to great eminence in the republic of letters; but, as a late

juvenile poet has observed of him-

Complete alike in head and heart, But wanting in the prudent part, He prov'd a poet's lot.

Of his poems no general character can be given. The subjects of them are sometimes uncommon and generally local or temporary. They are of course very unequal. But such of them as are in the Scottish dialect have been universally admired by his countrymen; and when it is considered that they were composed amidst a round of dislipation, they will be allowed to furnish complete

evidence of his genius and his tafte.

FERMAT (Peter), who was counfellor of the parliament of Toulouse in France, flourished in the 17th century, and died in 1663. He was a man of great talents, and a very general scholar; but being contemporary and intimately connected with Des Cartes, Mersenne, Torricelli, and Huygens, he was naturally led to devote much of his time to the mathematical sciences. He was (says Dr Hutton) a first rate mathematician, and possessed the sinest taste for pure and genuine geometry, which he contributed greatly to im-

prove, as well as algebra.

Fermat was author of, 1. A Method for the Quadrature of all forts of Parabolas. - 2. Another on Maximums and Minimums: which ferves not only for the determination of plane and folid problems, but also for drawing tangents to curve lines, finding the centres of gravity in folids, and the resolution of questions concerning numbers: in short, a method very similar to the fluxions of Newton .- 3. An Introduction to Geometric Loci, plane and folid. -4. A Treatife on Spherical Tangencies: where he demonstrates in the folids, the same things as Vieta demonstrated in planes .- 5. A Restoration of Apollonius's two books on Plane Loci. -6. A General Method for the dimension of Curve Lines. Besides a number of other smaller pieces, and many letters to learned men; feveral of which are to be found in his Opera Varia Mathematica, printed at Touloufe, in folio, 1679.

FERMENTATION is a chemical process which has been already considered in the Encyclopadia, and will be again resumed in this Supplement under the title Animal and Vegetable Substances. In this place we mean nothing more than to give such directions, prin-

cipally

Ter ita- cipally from Mr Richardson of Hull, for the proper fermentation of malt liquors as have not been fully detail-

ed in the article Brewing (Encycl.).

This author controverts, we do not think very fuccessfully, the conclusions drawn by Mr Henry from the experiments, of which the reader will find an account in the article FERMENTATION (Encycl.); but it is not his theory with which we are at present concerned, but his practice as that of an experienced, and enlightened brewer. Having treated of Worts, and the proper method of boiling them, for which fee WORT in this Supplement, and having given an historical view of the process of fermentation, of which a pretty accurate abridgement is inferted in the articles BREWING and FER-

MENTATION (Encycl.), he proceeds thus:

"The agency of air, in the business of fermentation, is very powerful; but as all fermentable subjects have an abundant supply, we are rather to provide for the egress of their own, than to fuffer the admission of the external air, by which a great number of the fine, volatile, oleaginous parts of the subject would be carried off, and a proportionate injury in flavour and spirituosity fustained. Hence such a covering should be provided for the gyle-tun as would barely allow the escape of the common air produced by the operation; whilft the gas, or fixed air, from its greater denfity, resting upon the furface of the beer the whole depth of the curb, prevents the action of the external air, and consequently the escape of those fine and valuable parts just men-

"But towards the conclusion of vinous fermentation, this aerial covering begins to lofe its efficacy; which points out the necessity of then getting the beer into casks as soon as possible, that the consequences may be prevented, of exposing so large a surface, liable to so copious an evaporation. Amongst these, a loss of spirituolity is not the least; for this evaporation is more and more spirituous, as the action approaches the completion of vinous fermentation; and that once obtained, the loss becomes still more considerable, if still exposed to the air; whence it might be termed the distillation of Nature, in which she is so much superior to art, that the ethereal spirit rises pure and unmixed, whilst the highest rectification of the still produces at best but a

compound of aqueous and spirituous parts.

"Nor is this entirely conjecture. Experience teaches us, that we cannot produce so strong a beer in summer, ceteris paribus, as in winter; the reason is, not because the action of fermentation does not realize fo much spirit in warm weather, but because the fermenting liquor, after the perfection of vinofity, continues so long in a state of rarefaction, that the spirituous parts are dissipated in a much greater degree at that time than at any other, in a similar state of progression. And this doctrine of natural distillation seems to account for that increase of strength obtainable from long preservation, in well closed casks, and, more particularly so, in glass bottles; for Nature, in her efforts to bring about her grand purpose of resolving every compound into its first principles, keeps up a perpetual internal struggle, as well as an external evaporation; and if the latter be effectually prevented, the former must be productive of additional spirituosity, so long as the action keeps within the pale of vinous fermentation.

"In order to maintain a due regulation of the ferment-SUPPL. Vol. I. Part II.

ing power, and to answer the several purposes of the Fezzan. operation, a scrupulous attention to the degree of heat at which the action commences, and a particular regard to the quality and quantity of the ferment employed, are indifpenfably necessary." The degree of heat must be ascertained by the thermometer, and regulated by experience: the quantity of yeast can be ascertained only by the intention of the artist; but of the quality of that substance we shall treat under YEAST in this Supplement.

FEZZAN is a kingdom in the anterior of Africa, placed in the vast wilderness as an island in the ocean. The following account of it was given to Mr Lucas the African traveller by an old shereef, a native of Fezzan; and that account was confirmed by the governor of Mesurata, who had himself visited Fezzan, and who, having treated the traveller with great kindness, ought not to be suspected of having wantonly deceived him.

According to this account, Fezzan is lituated to the fouth of Mesurata (see Mesurata in this Suppl.), and the traveller from the latter place to the former arrives in eight days at Wadan, where refreshments are procured for the caravan. From thence in five hours they reach the defart of Soudah, where no vegetable is feen to grow but the talk, a tree from which the lemon-coloured wood is taken which forms handles for tools. The passage of the desart takes up some days, when the traveller finds a miserable village, producing nothing but dates, brackish water, and Indian corn; from this village a day's journey conducts to the town of Sebbah, where are the remains of an ancient cattle, and other venerable ruins, and in four days more he reaches Mourzouk, the capital of Fezzan.

This city is fituated on the banks of a fmall river, furrounded by a high wall for defence, and is distant from Mesurata 390 computed miles. Eastward of Mourzook is the town of Queela, in which are the remains of ancient buildings; the fize of the cifterns, and the construction of the vaulted caves, exhibit instances of ancient splendor. South of which place is Jermah, distinguished by numerous and majestic ruins, on which are many inscriptions. Tessouwa lies eastward, near which was a river which the shereef remembers, but is now overwhelmed in the moving fands. N. E. from Mourzouk, distant about 120 miles, is the large town of Temmiswa, where the caravans of pilgrims from Bornou and Nigritia, by way of Cairo to Mecca, provide

their stores for the defart.

In the town or province of Mendrah is a large quantity of trona, a species of fosfil alkali, that floats on the furface or fettles on the banks of its spreading lakes, great quantity of which is fent to Tripoli and shipped for Turkey, Tunis, and Morocco; at the latter place it is used as an ingredient in the red dye of the leather. Mendrah is about 60 miles fouth of Fezzan. The territory of Fezzan extends but little westward, being confined by barren mountains. The smaller towns of this kingdom are faid to be about one hundred; thefe towns are chiefly inhabited by husbandmen and shepherds; in every town a market is regularly held; mutton and goat's flesh are sold by the quarter, usually from thirty-two to forty grains of gold, or from four to five shillings English. The slesh of camels is dearer, and divided into fmaller parts.

The houses are of clay, with flat roofs composed of branches Fezzan. branches of trees, on which earth is laid; this is fufficient in a climate where it never rains. The heats in fummer, from April to November, are intense, and the hot winds blow from the fouth-east, fouth, and fouthwest, with such violence as to threaten suffocation; when it changes to the west or north-west a reviving freshness

> The drefs of the inhabitants is like that of the Moors of Barbary, confifting of a large pair of trowlers, a shirt which hangs over the trowsers, a kind of waistcoat without sleeves, and a jacket with tight sleeves; over the jacket is a loofe robe which reaches below the knee, a girdle of crimfon, and a long cloth called a barrakon or alhaicque, like a highland plaid, is worn; stockings of leather, laced like half boots, and flippers; on the head a red cap and turban; fometimes over the whole they throw a long cloak with a hood, called a burnoofe. In summer they throw off all but the shirt and

> The people bear very high degrees of heat, but any cold affects them fenfibly. Their difeases are chiefly of the inflammatory and putrid kind; the small pox is common. Their old women are their principal physicians. For pains in the head they cup and bleed; for those in the limbs, they bathe in the hot lakes. They have a multitude of noxious and loathsome animals; the air is crowded with mosquitos, and their persons are over-run with the vermin which affect the beggars of

> In their persons they incline to the negro, of a deep fwarthy complexion, with curly black hair; they are tall, but indolent, inactive, and weak. In their common intercourfe, distinction of rank seems to be forgotten; rich and poor, master and man, converse, eat, and drink, together; they are, however, generous and

> An extensive plain composes the kingdom of Fezzan: the foil is generally a light fand, the fprings are abundant, and few regions in Africa exhibit a richer vegetation. The land produces the talk, the white-thorn, date trees, the olive and lime, apricot, pomegranate, and fig: Indian corn and barley are the favourite objects of cultivation, of wheat there is little raised. The tame animals are, the sheep, cow, goat, and camel; and the wild are, the offrich, antelopes of various kinds, one of which is called the huadee, which when chased plunges with address from a precipice, and lights on its

> The food of the lower class confifts of flour of Indian corn, feasoned with oil and fruit; those of superior rank eat wheat bread and flesh. Fezzan produces much falt; the water has in general a mineral tafte, but the favourite beverage is a liquor from the date tree, which acquires, when fermented, an intoxicating Arength. In religion they are rigid Mahomedans, but tolerant. Their government monarchical; their present king is descended from one of the shereefs of T'affilet, who about 400 years fince obtained the crown. Till the present century the kingdom was independent, when the Bashaw of Tripoli conquered and made it tributary; the reigning fovereign has nearly thrown off this yoke. In Fezzan, the descendants of the prophet are highly privileged, their property and persons are inviolable: they are exempt from certain punishments. This class are in general either princes or merchants.

The revenue is composed of a tax on towns and vil. Fez. lages, a tax on every camel load of goods (except provitions) which enters the capital, fines for offences, lands of persons dying without heirs, and a tax on gardens and date trees. Gold dust by weight is the chief medium of payment; but for convenience they are furnished with small papers of gold dust of different values, from two xarbes or one and a half upwards; for fmaller articles corn or flour are used as a medium. One grain of gold is equal to 11 d. sterling. The Fezzan grain is the fame as in England.

The justice of the fovereign is highly extolled; fmall offences are punished by the bastinado, and the punishments increase to fine, imprisonment, and death. Trusting to their natural defence, their towns are without guard, and they have no flanding forces. The only war the shereef remembered was undertaken against a people inhabiting the mountains of Tibesti, which is separated from the people of Fezzan by a wide and fandy defart. These people are wild and savage, and had plundered a caravan belonging to the king, who fent an army of between 3 and 4000 men against and subdued them. The country of these people produces much senna. The vales of Tibesti are said to be fertile in corn and pasture for cattle, particularly camels. The people live in huts, and profess various religions, fome the Mahomedan, others are attached to their ancient idolatry.

The people of Fezzan carry on a confiderable trade with Tripoli, Bornou, Nigritia, &c. At the end of October, when the heats are abated, the caravans depart from Mourzouk in small parties of ten or twelve, unless in time of war. They lay in provisions of dates, meal, and mutton falted, dried in the fun, and boiled in oil or fat. The merchants have agents in the chief towns, to whom they fend the flaves they purchase. The caravans to Tripoli carry the trona, fenna, gold and flaves brought from the fouthern countries; and in return bring back cutlery, woollen, filks, dollars, copper, and brafs.

That to Bornon carries brass and copper, for the currency of the country, imperial dollars, and various manufactures; but of their own produce only a preparation of dates, and meal of Indian corn, and they take in

return flaves, gold duft, and civet.

To Cashna, an empire in Nigritia, they carry cowries, brass to make rings and bracelets, horses, several kinds of manufactures, and the Gooroo nuts; and in return take gold duft, flaves, cotton cloth, dyed goats skins, hides, senna, and civet, for the countries south of the Niger, where also they convey fabre blades and Dutch knives, coral, brafs beads, looking glaffes, dollars, &c. and receive back gold dust, slaves, cotton cloths, goat kins, Gooroo nuts, cowries, and ivory.

A caravan of pilgrims sets out likewise in the autumn of every second or third year from Mourzouk, the capital of Fezzan, to Mecca. They proceed to Temessa, over the mountain of Ziltan, and thence to Sibbul, a place subject to Tripoli; and thence nearly in a line with the Mediterranean sea to Cairo, and thence

to Mecca by the customary route.

As not one celestial observation has been taken to determine any latitude between Benin and Tripoli, all the positions are fixed by estimation, reckoning fifteen or fixteen miles for a day's journey. Mr Rennell places

Mourzouk,

Mourzouk, the capital of Fezzan, in lat. 27°. 20', or - 260 miles from Masurata.

FIGURATE NUMBERS are fuch as do or may represent some geometrical figure, such as a triangle, pentagon, or pyramid, &c. These numbers are treated of at great length by Maclaurin in his Fluxions; Simpson in his Algebra; and Malcolm in his Arithmetic; but the following account of them by Dr Hutton is as

perspicuous as any that we have seen:

Figurate numbers are distinguished into orders, according to their place in the scale of their generation, being all produced one from another, viz. by adding continually the terms of any one, the successive sums are the terms of the next order, beginning from the first order, which is that of equal units 1, 1, 1, 1, &c.; then the 2d order consists of the successive sums of those of the 1st order, forming the arithmetical progression 1, 2, 3, 4, &c.; those of the 3d order are the successive sums of those of the 2d, and are the triangular numbers 1, 3, 6, 10, 15, &c.; those of the 4th order are the successive sums of those of those of the 3d, and are the py-tamidal numbers 1, 4, 10, 20, 35, &c.; and so on, as below:

Order. Name.	Numbers.							
Equals.	I,	1,	1,	I,	1,	&c.		
2. Arithmeticals,	1,	2,	3.	4,	5,	&c.		
3. Triangulars,	I,	3,	6,	10,	15,	&cc.		
4. Pyramidals,	1,	4,	10,	20,	35,	&c.		
5. 2d Pyramidals,	1,	5,	15,	35,	70,	&c.		
6. 3d Pyramidals,					126,			
7. 4th Pyramidals,	I,	7,	28,	84,	210,	&c.		

The above are all confidered as different forts of triangular numbers, being formed from an arithmetical progression whose common difference is 1. But if that common difference be 2, the successive sums will be the series of square numbers: if it be 3, the series will be pentagonal numbers, or pentagons; if it be 4, the series will be hexagonal numbers, or hexagons; and so on. Thus:

Arithme-			Ift Sun Polyg		2d Sums, or 2d Polygons.			
	1, 2, 3 1, 3, 5 1, 4, 7 1, 5, 9	, 7,	Tri. 1, 3 Sqrs. 1, 4 Pent. 1, 5 Hex. 1, 6	, 9, 16	1, 4, 10, 20 1, 5, 14, 30 1, 6, 18, 40 1, 7, 22, 50			

And the reason of the names triangles, squares, pentagons, hexagons, &c. is, that those numbers may be placed in the form of these regular figures or polygons, as here below:

OF SIL		7738	Triangl	es.						
	1	3	6		0	IC	0 0			
	0	0 0	00	0	000					
		.0	0 0		0 0					
		121012			of elected title					
Squares.										
1		4	9			-	6			
0	1	0		0	0	0	0	0		
		0		0	0	0	0	0		
			at wallen to			1193	-	116	142	

Pentagons.

1 5 12

When agons.

1 6 15

But the figurate pumbers of any order may also be found without computing those of the preceding orders; which is done by taking the successive products of as many of the terms of the arithmeticals 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the number which denominates the order of figurates required, and dividing those products always by the first product. Thus the triangular numbers are found by dividing the products 1 × 2, 2 × 3, 3 × 4, 4 × 5, &c. each by the first prod. 1 × 2; the first pyramids by dividing the products 1 × 2 × 3, 2 × 3 × 4, 3 × 4 × 5, &c. by the first 1 × 2 × 3. And in general, the figurate numbers of any order n, are found by substituting successively 1, 2, 3, 4, 5, &c. instead of x in this general

fucceffively 1, 2, 3, 4, 5, &c. inflead of x in this general expression $\frac{x \cdot x + 1 \cdot x + 2 \cdot x + 3}{1 \cdot 2 \cdot 3 \cdot 4} \cdot &c.$; where the sactors in the numerator and denominator are supposed to be multiplied together, and to be continued till the number in each be less by 1 than that which expresses

the order of the figurates required.

FILTER (See Encycl.) It is well known that veffels made of a particular kind of porous stone are employed as filtering basins for freeing water, intended to be drunk, from various kinds of impurity. In sea voyages such filtering basins must be highly useful; and they are frequently found useful at land where no water can be had but from stagnant pools, or springs slowing through clay. The stone, however, of which they are made is not every where to be found; and therefore different persons have endeavoured to employ the art of the poster to supply their place.

In the year 1790 a patent was granted to a female potter, for her invention of the following composition for this purpose; viz. four equal parts, out of nine equal parts, of tobacco-pipe clay; and five equal parts, out of nine equal parts, of coarse sea, river, drift, or pit fand; these two materials, in the above proportions, are fufficient for the purpose of making small basins, and other veffels, to contain a quantity not exceeding one gallon of water, or other liquid. But the compofition, when confined to these two materials, and in these proportions, often flies or cracks in the fire, if larger bafins, or other vessels, are attempted to be made with it. She, therefore, in the second instance, composes her filtering basins of equal parts of tobacco-pipe clay and coarse sea, river, drift, or pit sand; in the third instance, of three equal parts, out of nine equal parts, of tobacco-pipe clay; one equal part, out of nine equal parts, of Stourbridge clay, or clay from the furface of coal-mines, or any other clay of the fame quality; one equal part, out of nine equal parts, of Windfor, or other loam, of the same quality with Windsor loam; and sour equal parts, out of nine equal parts, of coarse river, sea, drift, or pit sand. Or, in the sourth instance, of sour equal parts, out of eight equal parts, of tobacco-pipe clay; three equal parts, out of eight equal parts, of coarse sea, river, drift, or pit sand; and one equal part, out of eight equal parts, of that burnt one equal part, out of eight equal parts, of that burnt and precipitated matter. With respect to the oil-trade, the space required is very great, especially for sperma-

If the lady who invented, or pretends to have invented, these basins, have a right to her patent, far be it from us to wish our readers of any description to incroach upon it; but as the use of the materials of which her basins are made was known to potters before she was born, they may certainly compound these materials in proportions different from hers, without doing her any legal injury. As she varies her own proportions so much, we think it probable that some proportion differing a little from them all, may answer the purpose of filtering vessels equally well; and it is almost needless to add, that with this precaution any potter may make such vessels, for which he would undoubtedly have a great demand.

A patent has likewise been granted to Mr Joshua Collier of Southwark for a very ingenious contrivance for filtering and sweetening water, oil, and all other liquids. Of this contrivance, which combines the application of machinery with the antiseptic properties of charcoal (See Chemistry N° 34. Supplement), we shall

give a detailed account.

Fish oil is one of the liquids which he had it particularly in view to free from all its impurities in fmell, tafte, and colour; and the chemical process employed by him for this purpose consists in pouring a quantity of any species of fish oil, or a mixture of different forts of fish oil, into any convenient vessel, which is to be heated to the temperature of 110 or 120 degrees of Fahrenheit's scale, and then adding of caustic mineral alkali, of the specific gravity commonly described as 1.25, or of fuch strength that a phial containing 1000 grains of distilled water will contain 1250 grains of these lees, a quantity equal to four parts of the 100 by weight of the quantity of oil; the mixture is then to be agitated, and left to stand a sufficient time for the falts and fediments to fubfide; it is then drawn off into another vessel, containing a sufficient quantity of fresh burnt charcoal, finely powdered, or any other fubstance possessing antiseptic properties, in a powdered or divided state, with an addition of a small proportion of diluted fulphuric acid, fufficient only to decompose the fmall quantity of faponaceous matter still suspended in the oil, which appears by the oil becoming clear at the furface: the contents of this veffel are also agitated, and the coaly faline and aqueous particles left to subfide; after which the oil is passed through proper strainers, herein after described, and is thereby rendered perfectly transparent and fit for use.

The principle of the improved strainers, or filtering machines, consists in the means applied to combine hydrostatic pressure, which increases according to the perpendicular height of the sluid, with the mode of filtering per ascensum, thereby procuring the new and peculiar advantage that the sluid and its sediment take opposite directions. A great advantage attending this invention is, that the dimensions of the chamber in which the sediment is received, may be varied, while the

chines not only to the purpose of families, work-houses. hospitals, public charities, the navy, or the merchant fervice, but also to all the purposes of oil-men, of distillers, of the laboratory, the brewery, &c. chambers of various capacities must be provided for the sediment and precipitated matter. With respect to the oil-trade, the space required is very great, especially for sperma. ceti, or Brasil bottoms. In the various purposes of the laboratory, no limits can be fixed, but all dimenfions will be occasionally required: in distilleries and breweries they may be fmaller in proportion; and in that defigned for water and for domestic use, a very fmall chamber will be fufficient. When water is to be fweetened, or freed from any putrid or noxious particles, it passes, in its way to the filtering chamber, through an iron-box, or cylinder, containing charcoal finely powdered, or any other antiseptic substance info. luble in water, the water being forced into it by hydrostatic pressure, through a tube of any sufficient height. This box has two apertures to receive and deliver the fluid, and thefe are opened and closed by cocks, or screws, or any other method used for such purposes, and being affixed to the machine by other screws, may be easily detached from the same. Thus, whenever the charcoal begins to lofe its antifeptic properties, the box is removed and heated till it is red hot; by which means the foreign matter escapes through the small apertures, after which the box is cooled, and the charcoal becomes fweet, pure, and equally fit for use as at first, though the process be ever so often repeated.

Another part of the invention confifts in filtering machines in the form of stills, in which charcoal may be repeatedly burned after any study substances have passed through it, for the purpose of freeing them either from putrid or noxious particles, or of discharging their colouring matter; which filtering stills are so contrived, that the study may pass through in any quantity, without displacing the charcoal: the part of the study remaining interspersed among the charcoal, may be driven over by heat, and be employed for many inferior purposes of the arts or manufactures. Lastly, the heat may be raised so as to purify the charcoal, as has been before described in the machines for water. The flue of those stills is so constructed that water may be employed to cool them without the loss of time requisite for their gradually parting with their heat to the furrounding atmosphere, so as to be fit for a subse-

quent operation.

But it was not merely to the purifying of oils and various liquids that Mr Collier turned his attention. To his filtering apparatus are attached instruments for ascertaining the comparative qualities of oils, which depend in part on the principle of their specific gravities; spermaceti oil, contrasted with other fish oils, being as 875 to 920. For this purpose, a glass vessel of any convenient shape, is made use of, furnished with a bubble also of glass, and a thermometer. If the oil is pure, this bubble finks, when the mercury rifes to a certain standard, by the application of the hand, or any other heat to the veffel containing the oil. If the spermaceti oil is impure, the bubble will still float, though it is of the temperature required; and the degree of impure, or foreign matter, will be shewn by the state of the thermometer at which the bubble finks.

To determine what tendency oils used for burning have to congeal in cold weather, a freezing mixture is put in a phial of thin glass, or any other convenient veffel; into this a thermometer is immerfed, and a fingle drop of the oil, under experiment, fuffered to fall on the outfide of the veffel, where it immediately congeals; as the cold produced by the mixture gradually ceases, it is easy to observe by the thermometer at what point of temperature the oil becomes fluid, and runs

down the side of the glass.

A short description of this apparatus will make its principles plain to every reader. A (fig. 1.) is the cistern, into which the water or other liquor to be filtered is put. B B, is a tube opening into the bottom of the ciftern A, and bent along the bottom of the machine conveying the fluid into CCC the filtering chamber, which is covered with leather bound down round its circular rim, and through which leather the water is percolated. D D, The bason rising above the level of the chamber and receiving the filtered liquor. E, The spout by which it runs off into a pitcher or other vessel. F, Another spout furnished with a cock to draw off the foul water from the chamber when necessary. G G G, The air tube, which begins above the level of the chamber, is covered with a button, which faves the leather from being cut, and has a fmall lateral aperture for the air to be carried off. This pipe passes along the bottom and up the side, and rifing above the level of the water in the ciftern, is there closed, except a fmall lateral aperture through which the air escapes. H, A guard or rim with cross bars put over the leather to keep it from being forced up by the water. It is fastened down by means of two notches on opposite sides of the guard, by which it locks into two staples rivetted into the bottom of the bason. I, The lid sliding down to cover the water from dust, and fuspended at pleasure by means of KK, two springs on each tube for that purpose. LM NO, A cylindrical box containing charcoal, which is connected with the above by means of the tube P, and a continuation of the tube B: L M, The water tube B continued below the charcoal apparatus, fo that the fluid may pass through the same into the cylinder, from whence it enters the chambers at P, fo as to be filtered through the leather as before described. RR, Collars which may be unferewed at pleasure, fo as to detach the charcoal apparatus whenever the charcoal requires to be purified by heat. SS, Two cocks to direct the fluid through the charcoal cylinder or immediately into the filtering chamber.

Fig. 2. A, A tub or cistern containing the oil to be filtered, and supplying a tube of sufficient height for the hydrostatic pressure to operate. BB, A main tube of wood, tin, leather, or cloth, to which any number of bags, of the fize and shape of corn facks, or any CC, convenient fize or shape may be connected. These are bound to DDD, straight double iron bars, furnished with a hinge at one end and a screw at the other, by opening which the bags may be emptied. F, A trough underneath, made to receive the filtered

oil from the receivers E E E.

Fig. 3. A, A funnel cask or cistern, into which the fluid is put which passes down. B, A tube fitted into the fame, through which it enters. C, An iron ftill, or still of any other substance capable of sustaining heat,

full of finely powdered and fifted charcoal, through the head of which the fluid passes into any receiver. D, A fire place of any construction to drive over the fluid remaining interspersed among the charcoal, and also to purify the charcoal by an increase of temperature when required. E, A cock to let water into the flues to cool the apparatus for a fubsequent operation.

Fig. 4. The trial glass with its thermometer.

FIRE. See that article Encycl. and CALORIC and COMBUSTION, CHEMISTRY-Index in this Suppl.

EXTINCTION OF FIRE is sometimes a matter of so much consequence, that every thing which promises to be effectual for that purpose is worthy of attention. In the nineteenth number of Mr Nicholfon's Journal of Philosophy, Chemistry, and the Arts, we have the following composition for extinguishing fire, invented by M. Von Aken.

pounds 30 Burnt alum Green vitriol powdered -40 Cinabrese or red ochre in powder -20 Potters' clay, or other clay, also powdered 200

With 40 measures of this mixture an artificial fire was extinguished under the direction of the inventor by three persons, which would have required the labour of 20 men and 1500 measures of common water. Sig. Fabbroni was commissioned to examine the value of this invention, and found in his comparative trials with engines of equal power, worked by the fame number of men, that the mixture extinguished the materials in combustion in one fixth part less time, and three eighths less of fluid than when common water was used. He obferved, as might indeed have been imagined from the nature of the material, that the flame disappeared whereever the mixture fell, and that the faline, metallic, and earthy matters formed an impenetrable lute round the hot combustible matter, which prevented the access of the air, and confequently the renewal of the destructive process.

This recipe, Mr Nicholfon informs us, is taken from the 85th No of the Giornale Letterario di Napoli, in which it was inferted in the form of a letter from Sig. Fabbroni to Sig. D. Luigi Targioni of Naples; and the author of the letter estimates the price of the com-

position at about one halfpenny per pound.

The reason affigned by Mr Nicholson for giving this abridged account a place in his valuable work, will be admitted by him and the public as a sufficient reason for our adopting it into our's. It is, that fuch inventions arc worthy of the attention of philosophers and economilts, even though in the first applications they may prove lefs advantageous than their inventors may be disposed to think. It is scarcely probable that this practice in the large way, with an engine throwing upwards of 200 gallons (value about L. 3, 10s.) each minute, would be thought of or adopted, or that a fufficient store of the materials would be kept in readiness; fince at this rate the expenditure for an hour would demand a provision to the amount of L. 210, sterling. But in country places the process, or some variation of it, might be applied with fufficient profit in the refult; more especially if it be considered that common falt or alum, or fuch faline matter as can be had and mixed with the water, together with clay, chalk, or lime, ochreous earth or common mud, or even these last without any falt, may answer the purpose of

the lute with more or less effect, and extinguish an accidental fire with much greater speed and certainty than clear water would do.

FIRE-Balls are meteors, of which some account has been given in the Encyclopadia, as well as of various hypotheles which have been framed respecting their nature and their origin. Since that article was published, a new and very fingular hypothesis lias been framed by Professor Chladni of Wittenberg, who maintains it by arguments, which, however fanciful, are yet worthy of Phil Mag. the reader's notice *.

mos 5 and 7.

He supposes, that fire balls, instead of being collections of the electrical fluid floating in the highest regions of our atmosphere, are masses of very dense matter formed in far distant parts of space, and subjected to fimilar laws with the planets and comets. He endeavours to prove, that their component parts must be dense and heavy; because their course shews, in so apparent a manner, the effects of gravity; and because their mass, though it distends to a monstrous size, retains sufficient consistency and weight to continue an exceedingly rapid movement through a very large space, without being decomposed or dissolved, notwithstanding the resistance of the atmosphere. It seems to him probable, that this substance is by the effect of fire reduced to a tough fluid condition; because its form appears fometimes round and-fometimes elongated, and as its extending till it burfts, as well as the burfting itfelf, allows us to suppose a previous capability of extension by elastic sluidity. At any rate it appears to be certain, that fuch denfe matter at fo great a height is not collected from particles to be found in our atmosphere, or can be thrown together into large masses by any power with which we are acquainted; that no power with which we are acquainted is able to give to fuch bodies so rapid a projectile force in a direction almost parallel to the horizon; that the matter does not rife upwards from the earth, but exists previously in the celestial regions, and must have been conveyed thence to our earth. In the opinion of Dr Chladni, the following is the only theory of this phenomenon that agrees with all the accounts hitherto given, which is not contrary to nature in any other respect, and which besides seems to be confirmed by various masses found on the spot where fire balls fell.

As earthy, metallic, and other particles form the principal component parts of our planets, among which iron is the prevailing part, other planetary bodies may therefore confift of fimilar, or perhaps the fame component parts, though combined and modified in a very different manner. There may also be dense matters accumulated in smaller masses, without being in immediate connection with the larger planetary bodies dispersed throughout infinite space; and which, being impelled either by some projecting power or attraction, continue to move until they approach the earth or fome other body, when, being overcome by its attractive force, , they immediately fall down. By their exceedingly great velocity, Rill increased by the attraction of the earth and the violent friction in the atmosphere, a ftrong electricity and heat must necessarily be excited; by which means they are reduced to a flaming and melted condition, and great quantities of vapour and different kinds of gafes are thus difengaged, which diftend the liquid mass to a montrous fize, till, by a still farther ex-

pansion of these classic fluids, it must at length burst. Pir Dr Chladni thinks also, that the greater part of the Shooting Stars, as they are called, are nothing else than fire balls; which differ only from the latter in this, that their peculiarly great velocity carries them past the earth at a greater distance, so that they are not so ftrongly attracted by it as to fall down; and therefore, in their passage through the high regions of the atmosohere, occasion only a transient electric flash, or actually take fire for a moment, and are again speedily extinguished, when they get to fuch a distance from the earth that the air becomes too much rarefied for the existence of fire.

The grounds on which Dr Chladni supports this opinion are various relations, well authenticated, of the motions of those meteors, and the phenomena which accompany their burfting. Befides those mentioned in the Encyclopadia, he lays a particular stress on the account which he received from M. Baudin, Professor of philofophy at Pau, of a remarkable fiery meteor feen in Gafcony on the 24th of July 1790. On the evening of that day M. Baudin was in the court of the castle of Marmes with a friend, the atmosphere being perfectly clear, when they fuddenly found themselves furrounded by a whitish light, which obscured that of the full moon, then shining with great lustre. On looking upwards, they observed, almost in their zenith, a fire ball of a larger diameter than the moon, and with a tail equal in length to five or fix times the diameter of the body. The ball and the tail were of a pale white colour, except the point of the latter, which was almost as red as blood. The direction of this meteor was from fouth to north.

"Scarcely (fays M. Baudin) had we looked at it for two feconds when it divided itself into several portions of confiderable fize, which we faw fall in different directions, and almost with the same appearance as the burfting of a bomb. All these different fragments became extinguished in the air; and some of them, in falling, affumed that blood-red colour which I had observed in the point of the tail. It is not improbable that all the rest may have assumed the same colour; but I remarked only those which proceeded in a direction towards Mormes, and which were particularly exposed to my view.

"About two minutes and a half, or three minutes after, we heard a dreadful clap of thunder, or rather explosion, as if several large pieces of ordnance had been fired off together. The concuffion of the atmosphere by this shock was so great, that we all thought an earthquake had taken place. The windows shook in their frames, and fome of them, which probably were laid to and not closely shut, were thrown open. We were informed next day, that in fome of the houses at Houga, a small town about half a mile distant from Mormes, the kitchen utenfils were thrown from the shelves; so that the people concluded there had been an earthquake. But as no movement was observed in the ground below our feet, I am inclined to think that all these effects were produced merely by the violent concussion of the atmosphere.

"We proceeded into the garden while the noise still continued and appeared to be in a perpendicular direction above us. Some time arter, when it had coafed, we heard a hollow noise, which seemed to roll along

the chain of the Pyrenees in echoes, for the distance of one of them ever proceeded upwards. All of them fifteen miles. It continued about four minutes, becoming gradually more remote, and always weaker; and at the same time we perceived a strong smell of sulphur.

"While we were endeavouring to point out to some persons present the place where the meteor had divided itself, we observed a small whitish cloud, which arose perhaps from the vapour of it, and which concealed from us the three stars of the Great Bear, lying in the middle of those forming the semicircle. With some difficulty, however, we could at last distinguish these flars again behind the thin cloud. There arose, at the

same time, a fresh gentle breeze.

" From the time that elapsed between the bursting of the ball and the explosion which followed, I was inclined to think, that the meteor was at the height of at least feven or eight miles, and that it fell four miles to the north of Mormes. 'The latter part of my conjecture was foon confirmed by an account which we received, that a great many stones had fallen from the atmosphere at Juliac, and in the neighbourhood of Barbotan. One of these places lies at the distance of about four miles to the north of Mormes, and the other at about the distance of five to the north-northwest."

M. de Carrits Barbotan, the friend who was with the Professor in the court and garden of Mormes when the meteor first attracted their attention, was at Juliac two days afterwards, and confirmed to him the truth of this circumstance. It appeared, likewise, from the account of several intelligent persons, highly worthy of credit, that the meteor burst at a little distance from Juliac, and that the stones which fell were found lying in a space almost circular, about two miles in diameter. They were of various fizes. Some were feen to fall, which, when found, weighed 18 or 20 pounds, and which had funk into the earth from two to three feet. M. de C. Barbotan transmitted one weighing 18 pounds to the academy of sciences at Paris; and M. Baudin was told, that some were found which weighed even 50 pounds. He examined a small one, and found it very heavy in proportion to its fize: it was black on the outside; of a greyish colour in the inside, and interfperfed with a number of small shining metallic particles. On striking it with a piece of steel, it produced a few small dark red sparks, not very lively. A mineralogist, to whom a like piece of stone from the same meteor was shewn at Paris, described it as a kind of grey flag mixed with calcareous spar, the surface of which exhibited vitrified blackish calx of iron. The Professor was told also, that some stones were found totally vitrified.

Such (fays Dr Chladni) is the account given by Baudin of this meteor; the phenomena of which he endeavours to explain from accumulations in the upper

parts of the atmosphere.

According to all the observations hitherto made with any accuracy on fire-balls, the height at which they were first perceived was always very considerable, and by comparing the angles under which they were feen from different points, often 19 German miles, and even more; their velocity, for the most part, several miles in a fecond; and their fize always very great, often a quarter of a mile, and even more, in diameter. They were all feen to fall mostly in an oblique direction; not toughness of the principal component parts of fire-balls,

have appeared under the form of a globular mass, sometimes a little extended in length and highly luminous; having behind it a tail, which, according to every appearance, was composed of flames and smoke. All of them burst after they were seen to move through a large fpace, sometimes over several districts, with an explosion which shook every thing around. In every instance where there has been an opportunity of observing the fragments that fell after they burit, and which sometimes have funk to the depth of several feet into the earth, they were found to confift of scorious masses, which contained iron in a metallic or calcined state, pure, or else mixed with different kinds of earth and fulphur. All the ancient and modern accounts, written partly by naturalists and partly by others, are so effentially fimilar, that the one feems to be only a repetition of the other. This conformity in accounts. the authors of which knew nothing of those given by others, and who could have no interest in fabricating fimilar tales, can scarcely have arisen from accident or fiction, and gives to the related facts, however inexplicable many of them may feem, every degree of credibility.

In the third volume of Pallas's Travels, we have an account of a mass of iron discovered by him in Siberia, which Dr Chladni confiders as having been undoubted. ly a fire-ball, or the fragment of a fire-ball. This problematical mass was found between Krasnojarsk and A. bekansk in the high slate mountains, quite open and uncovered. It weighed 1600 pounds; had a very irregular and fomewhat compressed figure like a rough granite; was covered externally with a ferruginous kind of crust; and the inside consisted of malleable iron. brittle when heated, porous like a large sea sponge, and having its interffices filled with a brittle hard vitrified fubstance of an amber yellow colour. This texture and the vitrified substance appeared uniformly throughout the whole mass, and without any traces of flag or

artificial fire.

Dr Chladni shews, with a great deal of ingenuity. that this mass neither originated by the wet method, nor could have been produced by art, the burning of a forest, by lightning, or by a volcanic eruption. It appears to him, therefore, in the highest degree probable, that it is of the same nature with fire-balls, or, as they have fometimes been called, flying dragons. The Tartars, as we are informed by Pallas, confidered this male as a facred relic which had dropped down from heaven; and this circumstance Dr Chladni considers as no flight confirmation of his opinion, which he farther fup-

ports by the following reasonings:

"1. As fire balls confift of dense and heavy substances, which, by their exceedingly quick movement, and the friction thence excited by the atmosphere, become electric, are reduced to a state of ignition, and melted by the heat, fo that they extend to a great fize, and burst; it thence follows, that in places where fragments, produced by the burfting of a fire-ball, have been found, substances endowed with all these properties must alsohave been found. Iron, however, the principal component part of all the maffes hitherto found (and he speaks of many befides that of Pallas), possesses all these properties in a very eminent degree. The weight and

IR which must be very considerable, since, with the great- by what means they were brought into such an infuest possible distention, they retain consistence enough to proceed with the utmost velocity through such an immense space without decomposition of their mass, and without their progress being obstructed by the resistance of the air, agree perfectly well with melted iron; their dazzling white light has by many observers been compared to that of melted iron; iron also exhibits the same appearances of flaming, smoking, and throwing out sparks, and all these phenomena are most beautiful when they take place in vital air. Of the extension by elastic sluids expanded by the heat, and of the contraction which follows from cold, traces may be discovered in the internal fpongy nature of the iron masses which have been found, and in the globular depressions of the exterior hard crust; the latter of which gives us reason to suppose, that in these places there have been airbubbles, which, on cooling, funk down. The mixture of fulphur found in various maffes, agrees also exceedingly well with the phenomena of fire balls, and especially with the great inflammability of fulphur in very thin impure air; for it is well known, that fulphur in an air-pump will take fire in air in which few other bodies

could do the fame. In regard to those masses in which no fulphur was fourd, this may have arisen from the

fulphur escaping in vapour, fince some time after the appearance of fire balls a strong smell of sulphur has

been perceived. The brittleness of the Siberian iron

mass when heated, may arise from some small remains

of fulphur, which may perhaps be the cause of the facility with which fragments of this mass, as well as of

another found at Aix-la Chapelle, could be roasted. " 2. The whole texture of the masses betrayed evident figns of fusion. This, however, cannot have been occasioned by any common, natural, or artificial fire; and particularly for this reason, because iron so malleable is not fulible in such fire, and when it is fuled with the addition of inflammable matters, loses its malleability, and becomes like common raw iron. The vitrified fubstance in the Siberian mass is equally incapable of being fuled in a common fire. The fire, then, must have been much stronger than that produced by the common, natural, and artificial means; or the fusion must have been effected by the force of exceedingly strong electricity; or perhaps both causes may have been com-

bined together.

" 3. It is totally incomprehenfible how, on the high flate mountains, where the Siberian mass was found, at a confiderable distance from the iron mines; in the chalky foil of the extensive plains of America, where for a hundred miles around there are no iron mines, and not even fo much as a stone to be found; and at Aix la-Chapelle, where, as far as the author knows, there are no iron works-fo many ferruginous particles could be collected in a fmall space as would be necesfary to form masses of 1600, 15,000, and 17,000, up to 33,600 pounds. This circumstance shews, that these masses could as little have been fused by lightning as by the burning of a forest or of fossile coal. These masses were found quite exposed and uncovered, and not at any depth in the earth, where we can much more readily admit fuch an accumulation of ferruginous particles to have been melted by the effects of light-

"Should it be asked, how such masses originated, or

lated position? this question would be the same as if it were asked how the planets originated. Whatever hy. potheses we may form, we must either admit that the planets, if we except the many revolutions which they may have undergone, either on or near their surface. have always been fince their first formation, and ever will be the same; or that nature, acting on created matter, possesses the power to produce worlds and whole fystems, to destroy them, and from their materials to form new ones. For the latter opinion there are, indeed, more grounds than for the former, as alternations of destruction and creation are exhibited by all organifed and unorganifed bodies on our earth; which gives us reason to suspect that nature, to which greatness and fmallness, confidered in general, are merely relative terms, can produce more effects of the same kind on a larger scale. But many variations have been observed on distant bodies, which, in some measure, render the last opinion probable. For example, the appearing and total disappearing of certain stars, when they do not depend upon periodical changes. If we now admit that planetary bodies have flarted into existence, we cannot suppose that such an event can have otherwise taken place, than by conjecturing that either particles of matter, which were before dispersed through infinite space in a more soft and chaotic condition, have united together in large masses by the power of attraction; or that new planetary bodies have been formed from the fragments of much larger ones that have been broken to pieces, either perhaps by some external shock, or by an internal explosion. Let whichever of these hypotheses be the truest, it is not improbable, or at least not contrary to nature, if we suppose that a large quantity of fuch material particles, either on account of their too great distance, or because prevented by a stronger movement in another direction, may not have united themselves to the larger accumulating mass of a new world; but have remained infulated, and, impelled by fome shock, have continued their course through infinite space, until they approached so near to some planet as to be within the sphere of its attraction, and then by falling down to occasion the phenomena before mentioned."

Whether Chladni be a philosopher of the French school we know not; but some parts of his theory tend strongly towards materialism; and the arguments by which he attempts to prop those parts are peculiar. ly weak. When he talks of Nature producing worlds, he either substitutes Nature for Nature's God, or utters jargon which has no meaning. In what fense the word Nature is used by every philosopher of a found mind, we have elsewhere been at some pains to shew (see River, no 116. Encycl.); but how absurd would it be to fay, that the fystem of general laws, by which the Author and Governor of the universe connects together its various parts, and regulates all their operations, possesses, independently of him, "the power to produce worlds and whole fystems, to destroy them, and from their materials to form new ones!"

As Chladni admits, or talks as if he admitted, the creation of matter, it would be wrong to impute to him this absurdity; but if by Nature he means God, and he can confiftently mean nothing elfe, we beg leave to affirm, that it is directly contrary to every notion

which we can form of Nature in this fense, "to suppose emperor Leo, when the Orientals attacked Constantithat a large quantity of material particles, either on account of their distance, or because prevented by a stronger movement in another direction, have not united themfelves to the larger accumulating mass of a new world, but remained infulated, and impelled by fome shock, have continued their course through infinite space, &c.". Is there any distance to which God cannot reach, or any movement fo strong as to refit his power? Our author's language is indeed confused, and probably his ideas were not very clear. When he speaks of the particles of matter being at first dispersed through infinite space, and afterwards united by the power of attraction, he revives the question which was long ago difcuffed between Newton and Bentley, and discuffed in fuch a manner as should have silenced for ever the babblings of those who form worlds by attraction.

"The hypothesis (says Newton) of matter's being at first evenly spread through the heavens, is, in my opinion, inconsistent with the hypothesis of innate gravity without a supernatural power to reconcile them; and therefore infers a Deity. For if there be innate gravity, it is impossible now for the matter of the earth, and all the planets and stars, to fly up from them, and become evenly spread through all the heavens, without a supernatural power; and certainly that which can never be hereafter without a supernatural power, could never be heretofore without the same power." Dr Chladni, indeed, does not say that his particles of matter were evenly dispersed through infinite space; but such must be his meaning, if he has any meaning: for matter unevenly dispersed must, by an innate attraction, be united as foon as it exists, and so united as not to leave small fragments of it to wander, we know not why, through the trackless void. Turn matter on all sides, make it eternal or of late production, finite or infinite, there can be no regular fystem produced but by a voluntary and meaning agent; and therefore, if it be true that fire balls are masses of dense matter, coeval with the planetary system, existing in the celestial regions, and thence conveyed to our earth, they must have been formed, and their motions impressed upon them, by the Author of Nature for some wife purpose, though by us that purpose may never be discovered. One thing feems pretty clear, that wherever they may be formed, the phenomena attending their bursting, account fufficiently for the notions of thunderbolts which have been generally entertained in all ages, and in every country.

Greek-FIRE (fee Wild-FIRE, Encycl.). In the fecond volume of Mr Nicholfon's Philofophical Journal, we have the following receipt for making this composition, taken from some manuscripts of Leonard de Vinci, who flourished in the end of the fifteenth and beginning of the fixteenth centuries, and who appears to have advanced far before his contemporaries in physical science. Take the charcoal of willow, nitre, brandy, refin, fulphur, pitch, and camphor. Mix the whole together over the fire. Plunge a woollen cord in the mixture, and form it into balls, which may afterwards be provided with spikes. These balls, being set on fire, are thrown into the enemy's veffels. It is called the Greek fire, and is a fingular composition, for it burns even upon the water. Callinicus the architect taught this compolition to the Romans (of Constantinople), who derived great advantage from it, particularly under the SUPPL. VOL. I. Part II.

nople. A great number of their vessels were burned by means of this composition.

The composition of the Greek fire thus given by Vinci is found in nearly the same words in some of the writings of Baptista Porta; whence it appears that both authors derived their information from the same source. A composition which burnt without access to the atmosphere could not fail to fill the minds of our forefathers with wonder; but the modern discoveries in chemistry have disclosed the secret, by shewing, that the combustion is carried on by means of the oxygen contained in the nitre.

Rafant or Razant Fire, is a fire from the artillery and small arms, directed parallel to the horizon, or to those parts of the works of a place that are defended.

Running FIRE is when ranks of men fire one after another; or when the lines of an army are drawn out to fire on account of a victory; in which case each squadron or battalion takes the fire from that on its right, from the right of the first line to the left, and from the left to the right of the second line, &c.

FISHING, the art of catching fish. See Angling,

FISHERY, and FISHING, &c. Encycl.

Chinese Fishing. We venture to give this appellation to some very ingenious contrivances of the people of China for catching in their lakes, not only fift, but water fowl. For the purpose of catching fish they have trained a species of pelican, refembling the common corvotant, which they call the Leu-tze, or fishing bird. It it brown, with a white throat, the body whitish beneath, and spotted with brown; the tail is rounded, the irides blue, and the bill yellow. Sir George Staunton, who, when the embaffy was proceeding on the fouthern branch of the great canal, faw those birds employed, tells us, that on a large lake, close to the east fide of the canal, are thousands of small boats and rafts, built entirely for this species of fishery. On each boat or raft are ten or a dozen birds, which, at a fignal from the owner, plunge into the water; and it is altonishing to fee the enormous fize of fish with which they return, grasped within their bills. They appeared to be so well trained, that it did not require either ring or cord about their throats to prevent them from swallowing any portion of their prey, except what their master was pleased to return to them for encouragement and food. The boat used by these sishermen is of a remarkable light make, and is often carried to the lake, together with the fishing birds, by the men who are there to be sup-

The fame author faw the fishermen bufy on the great lake Wee chaung-hee; and he gives the following account of a very fingular method practifed by them for catching the fish of the lake without the aid of birds. of net, or of hooks.

To one fide of a boat a flat board, painted white, is fixed, at an angle of about 45 degrees, the edge inelining towards the water. On moonlight nights the boat is fo placed that the painted board is turned to the moon, from whence the rays of light striking on the whitened furface, give to it the appearance of moving water; on which the fish being tempted to leap as on their element, the boatmen raising with a ftring the board, turn the fish into the boat.

Water fowl are much fought after by the Chinefe,

and are taken upon the fame lake by the following ingenious device. Empty jars or gourds are fuffered to float about upon the water, that fuch objects may become familiar to the birds. The fisherman then wades into the lake with one of those empty vessels upon his head, and walks gently towards a bird; and lifting up his arm, draws it down below the surface of the water without any disturbance or giving alarm to the rest, several of whom he treats in the same manner, until he fills the bag he had brought to hold his prey. The contrivance itself is not so singular, as it is that the same exactly should have occurred in the new continent, as Ulloa afferts, to the natives of Carthagena, upon the lake Cienega de Tesias.

FISTULA LACHRYMALIS is a difease which, in all its stages, has been treated of in the article Surgery, chap. xiv. Encycl. A work, however, has been lately published by James Ware surgeon, in which there is the description of an operation for its cure considerably different from that most commonly used, and which, while it is simple, the author's experience has ascertain-

ed to be successful.

In the cure of this disease, which is very troublesome, and not very uncommon, it is a well known practice to insert a metallic tube in the nasal duct of the lachrymal canal: but the advantage derived from this operation is not at all times lasting. Among other causes of failure, Mr Ware notices the lodgment of inspissated mucus in the cavity of the tube. To remedy this de-

fect, he recommends the following operation.

" If the disease has not occasioned an aperture in the lachrymal fac, or if this aperture be not fituated in a right line with the longitudinal direction of the nafal duct, a puncture should be made into the sac, at a small distance from the internal juncture of the palpebræ, and nearly in a line drawn horizontally from this juncture towards the nofe with a spear-pointed lancet. The blunt end of a filver probe, of a fize rather smaller than the probes that are commonly used by surgeons, should then be introduced through the wound, and gently, but steadily, pushed on in the direction of the nasal duct, with a force sufficient to overcome the obstruction in this canal, and until there is reason to believe that it has freely entered into the cavity of the nose. The position of the probe, when thus introduced, will be nearly perpendicular; its fide will touch the upper edge of the orbit; and the space between its bulbous end in the nose and the wound in the skin will usually be found, in a full-grown person, to be about an inch and a quarter, or an inch and three-eighths. The probe is then to be withdrawn, and a filver style, of a fize nearly fimilar to that of the probe, but rather smaller, about an inch and three-eighths in length, with a flat head, like that of a nail, but placed obliquely, that it may fit close on the skin, is to be introduced through the duct, in place of the probe, and to be left constantly in it. For the first day or two after the style has been introduced, it is fometimes advisable to wash the eye with a weak faturnine lotion, in order to obviate any tendency to inflammation which may have been excited by the operation; but this in general is fo flight, that our author has rarely had occasion to use any application to remove it. The ftyle should be withdrawn once every day for about a week, and afterwards every fecond or third day. Some warm water

fhould each time be injected through the dust into the role, and the instrument be afterwards replaced in the fame mauner as before. Mr Ware formerly used to cover the head of the style with a piece of diachylon plaster spread on black silk, but has of late obviated the necessity for applying any plaster by blackening

the head of the ftyle with fealing wax.

"The effect (fays he) produced by the style, when introduced in the way above mentioned, at first gave me much furprise. It was employed with a view similar to that with which Mr Pott recommends the introduction of a bougie; viz. to open and dilate the nasal duct, and thus to establish a passage, through which the tears might afterwards be conveyed from the eye to the nose. I expected, however, that whilst the style continued in the duct the obstruction would remain, and of course that the watering of the eye, and the weakness of the fight, would prove as troublesome as they had been before the instrument was introduced. I did not imagine that any effential benefit could refult from the operation until the style was removed, and the passage thereby opened. It was an agreeable disappointment to me to find that the amendment was much more expeditious. The watering of the eye almost wholly ceased as soon as the style was introduced; and in proportion as the patient amended in this respect, his fight also became more strong and useful. The style, therefore, feems to act in a twofold capacity: first, it dilates the obstructed passage; and then, by an attraction somewhat similar to that of a capillary tube, it guides the tears through the duct into the nofe.

"The wound that I usually make into the fac, if the supperative process has not formed a suitable aperture in this part, is no larger than is just sufficient to admit the end of the probe or style; and this, in general, in a little time, becomes a sistulous orifice, through which the style is passed without occasioning the smallest degree of pain. The accumulation of matter in the lachrymal sac, which, previous to the operation, is often copious, usually abates soon after the operation has been performed; and, in about a week or ten days, the treatment of the case becomes so easy, that the patient himself, or some friend or servant who is coultantly with him, is sully competent to do the whole that is necessary. It consists solely in withdrawing the style two or three times in the week, occasionally injecting some warm water, and then replacing the instrument in the

fame way in which it was done before.

"It is not easy to ascertain the exact length of time that the style should be continued in the duct. Some have worn it many years, and, not finding any inconvenience from the instrument, are still as and unwilling to part from it. Others, on the contrary, have disused it at the end of about a month or fix weeks, and have not had the smallest return of the obstruction asterwards."

The author relates fo many fuccessful cases of this operation, that we thought it our duty to record his method in this Supplementary volume of our general repository of arts and sciences; for a successful practice, as well in surgery as in physic, must rest on the basis of

experience.

Oblique or Second FLANK, or FLANK of the Curtain, is that part of the curtain from whence the face of the opposite bastion can be seen, being contained between the lines rasant and sichant, or the greater

tween the flank and the point where the fichant line of defence terminates.

Covered, Low, or Retired FLANK, is the platform of the casemate, which lies hid in the bastion, and is other.

wife called the orillon.

Fichant FLANK, is that from whence a cannon playing, fires directly on the face of the opposite bastion.

Rafant or Razant FLANK, is the point from whence the line of defence begins, from the conjunction of which with the curtain the shot only raseth the face of the next bastion, which happens when the face cannot be discovered but from the flank alone.

FLIE or FLY, that part of the mariner's compass on which the thirty-two points of the wind are drawn, and over which the needle is placed, and faltened under-

neath.

FLOATING Bodies are fuch as swim on the furface of a fluid, of which the most important are ships and all kinds of veffels employed in war and in commerce. Every feaman knows of how much consequence it is to determine the stability of such vessels, and the positions which they assume when they float freely and at rest on the water. To accomplish this, it is necessary to state the principles on which that stability and these positions depend; and this has been done with so much ingenuity and science by George Atwood, Esq; F. R. S. in the Philosophical Transactions for the year 1796, that we are perfuaded a large class of our readers will thank us for inferting an abstract of his memoir in

this place.

A floating body is prefied downwards by its own weight in a vertical line that paffes through its centre of gravity; and it is fustained by the upward pressure of a fluid, acting in a vertical line that passes through the centre of gravity of the immersed part; and unless these two lines be coincident, so that the two centres of gravity may be in the fame verticle line, the folid will revolve on an axis, till it gains a position in which the equilibrium of floating will be permanent. Hence it appears that it is necessary, in the first place, to ascertain the proportion of the part immerfed to the whole; for which purpose the specific gravity of the floating body must be known; and then it must be determined, by geometrical or analytical methods, in what positions the solid can be placed on the surface of the fluid, fo that the two centres of gravity already mentioned may be in the fame vertical line when a given part of the folid is immerfed under the furface of the fluid. When these preliminaries are settled, something still remains to be done. Positions may be assumed in which the circumstances just recited concur, and yet the folid will assume some other position in which it will permanently float. If a cylinder, e. g. having its specific gravity to that of the fluid on which it floats as 3 to 4, and its axis to the diameter of the base as 2 to t, be placed on the fluid with its axis vertical, it will fink to a depth equal to a diameter and a half of the base; and while its axis is preserved in a vertical position by external force, the centres of gravity of the whole folid and of the immerfed part will remain in the same vertical line: but when the external force that fustained it is removed, it will decline from its upright position, and will permanently float with its axis horizontal. If the axis be supposed to be half of the dia-

and less lines of defence; or the part of the curtain be- meter of the base, and be placed vertically, the solid Floating. will fink to the depth of three-eighths of its diameter; and in that position it will float permanently. If the axis be made to incline to the vertical line, the folid will change its position until it settles permanently with

the axis perpendicular to the horizon.

Whether, therefore, a folid floats permanently, or oversets when placed on the surface of a fluid, so that the centre of gravity of the folid and that of the part immersed shall be in the same vertical line, it is said to be in a position of equilibrium; and of this equilibrium there are three species, viz. the equilibrium of stability, in which the folid floats permanently in a given position; the equilibrium of inflability, in which the folid, though the two centres of gravity already mentioned are in the same vertical line, spontaneously oversets, unless supported by external force; and the equilibrium of indifference, or the infensible equilibrium, in which the folid refts on the fluid indifferent to motion, without tendency to right itself when inclined, or to incline itself farther.

If a folid body floats permanently on the furface of a fluid, and external force be applied to incline it from its position, the resistance opposed to this inclination is termed the stability of floating. Among various floating bodies, some lose their quiescent position, and some gain it, after it has been interrupted, with greater fa-

cility and force than others.

Some ships at sea (e.g.) yield to a given impulse of the wind, and fuffer a greater inclination from the perpendicular than others As this refistance to lieeling or pitching, duly regulated, has been deemed of importance in the construction of vessels, several emineut mathematicians have investigated rules for determining the stability of ships from their known dimensions and weight, without recurring to actual trial. To this class we may refer Bouguer, Euler, Fred. Chapman, and others; who have laid down theorems for this purpose, founded on a supposition that the inclinations of ships from their quiescent positions are evanescent, or, in a practical fense, very small.

"But ships at sea (says our ingenious author) are known to heel through angles of 10°, 20°, or even 300, and therefore a doubt may arise how far the rules, demonstrated on the express condition that the angles of inclination are of evanescent magnitude, should be admitted as practically applicable in cases where the inclinations are so great."—" If we admit that the theory of statics can be applied with any effect to the practice of naval architecture, it seems to be necessary that the rules, investigated for determining the stability of vessels, should be extended to those cases in which the angles of inclination are of any magnitude likely to

occur in the practice of navigation."

A folid body placed on the surface of a lighter fluid, at the depth corresponding to the relative gravities, cannot change its position by the combined actions of its weight and the pressure of the fluid, except by revolving on some horizontal axis which passes through the centre of gravity: but as many axes may be drawn through this point of the floating body in a direction parallel to the horizon, and the motion of the folid respects one axis only, this axis must be determined by the figure of the body and the particular nature of the case. When this axis of motion, as it is called, is deFloating termined, and the specific gravity of the folid is known, "the politions of permanent floating will be obtained, first by finding the several positions of equilibrium through which the folid may be conceived to pass, while it revolves round the axis of motion; and fecondly, by determining in which of those positions the equilibrium is permanent, and in which of them it is

momentary and unstable."

Such as we have now briefly flated are the general principles, on which are founded Mr Atwood's inveftigations for determining the politions affumed by homogeneous bodies, floating on a fluid furface; and alfo for determining the stability of ships and of other sloating bodies. We cannot farther accompany him in his elucidation of them, in the problems to the folution of which they lead, and in the important practical purposes of naval architecture to which they are referred The whole paper, comprehending no less than 85 pages, is curious and valuable; it abounds with analytical and geometrical disquisitions of the most elaborate kind; and it serves to enlarge our acquaintance with a subject that is not only highly interesting to the speculative mathematician, but extremely useful in its practical application.

With this latter view, the author feems to have directed his attention to the various objects of inquiry which this article comprehends. They are fuch as intimately relate to the theory of naval architecture, fo far as it depends on the pure laws of mechanics, and they contribute to extend and improve this theory. The union of those principles that are deduced from the laws of motion, with the knowledge which is devived from observation and experience, cannot fail to establish the art of constructing vessels on its true basis, and gradually to lead to farther improvements of the greatest importance and utility. To this purpose, the

author observes, that

" If the proportions and dimensions adopted in the construction of individual vessels are obtained by exact geometrical menfurations, and calculations founded on them, and observations are made on the performance of these vessels at sea; experiments of this kind, sufficiently diversified and extended, seem to be the proper grounds on which theory may be effectually applied in developing and reducing to fystem those intricate, subtil, and hitherto unperceived causes, which contribute to impart the greatest degree of excellence to vessels of every species and description. Since naval architecture is reckoned amongst the practical branches of science, every voyage may be confidered as an experiment, or rather as a feries of experiments, from which useful truths are to be inferred towards perfecting the art of constructing vessels: but inferences of this kind, confiftently with the preceding remark, cannot well be obtained, except by acquiring a perfect knowledge of all the proportions and dimensions of each part of the thip; and fecondly, by making and recording fufficiently numerous observations on the qualities of the vessel, in all the varieties of fituation to which a ship is usually liable in the practice of navigation."

In the valuable miscellany entitled the Philosophical Magazine, there is a paper on this subject by Mr John George English, teacher of mathematics and mechanical philosophy; which, as it is not long, and is easily understood, we shall take the liberty to transcribe.

" However operofe and difficult the calculations ne. Floa, ceffary to determine the stability of nautical vessels may, in some cases, be, yet they all depend, says this author, upon the four following simple and obvious theorems, accompanied with other well known flereometrical and flatical principles.

" Theorem 1. Every floating body displaces a quantity of the fluid in which it floats, equal to its own weight: and confequently, the specific gravity of the fluid will be to that of the fluating body, as the magnitude of the whole is to that of the part immer-

"Theorem 2. Every floating body is impelled downward by its own effential power, acting in the direction of a vertical line passing through the centre of gravity of the whole; and is impelled upward by the re-action of the fluid which supports it, acting in the direction of a vertical line paffing through the centre of gravity of the part immersed: therefore, unless these two lines. are coincident, the floating body thus impelled muft revolve round an axis, either in motion or at rest, until the equilibrium is restored.

"Theorem 3. If by any power whatever a vessel be deflected from an upright position, the perpendicular distance between two vertical lines passing through the centres of gravity of the whole, and of the part immerfed respectively, will be as the stability of the vessel, and which will be positive, nothing, or negative, according as the metacentre is above, coincident with, or

below, the centre of gravity of the vessel.
"Theorem 4. The common centre of gravity of any fystem of bodies being given in position, if any one of these bodies be moved from one part of the system to another, the corresponding motion of the common centre of gravity, estimated in any given direction, will be to that of the aforesaid body, estimated in the same direction, as the weight of the body moved is to that of the whole fystem.

" From whence it is evident, that in order to afcertain the stability of any vessel, the position of the centres of gravity of the whole, and of the part immerfed, must be determined; with which, and the dimensions of the vessel, the line of floatation, and angle of deflection, the stability or power either to right it-

felf or overturn; may be found.

"In ships of war and merchandise, the calculations necessary for this purpose become unavoidably very operofe and troublesome; but they may be much facilitated by the experimental method pointed out in the New Transactions of the Swedish Academy of Scien-

ces, first quarter of the year 1787, page 48.

"In river and canal boats, the regularity and fimplicity of the form of the veffel itself, together with the compact disposition and homogeneal quality of the burden, render that method for them unnecessary, and make the requisite calculations become very easy. Veffels of this kind are generally of the same transverse fection throughout their whole length, except a small part in prow and thern, formed by segments of circles or other fimple curves; therefore a length may eafily be affigned fuch, that any of the transverse sections being multiplied thereby, the product will be equal to the whole folidity of the vessel. The form of the section ABCD is for the most part either rectangular, as in fig. 1. trapezoidal as in fig. 2. or mixFing. tilineal as in fig. 3. in all which MM represents the line of floatation when upright, and EF that when inclined at any angle MXE; also G represents the centre of gravity of the whole vessel, and R that of the

part immersed.

"If the veffel be loaded quite up to the line AB, and the specific gravity of the boat and burden be the fame, then the point G is simply the centre of gravity of the section ABCD; but if not, the centres of gravity of the boat and burden must be found separately, and reduced to one by the common method, namely, by dividing the fum of the momenta by the fum of weights, or areas, which in this case are as the weights. The point R is always the centre of gravity of the fection MMCD, which, if confifting of different figures, must also be found by dividing the fum of the momenta by the fum of the weights as common. These two points being found, the next thing necessary is to determine the area of the two equal triangles MXE, MXF, their centres of gravity o, o, and the perpendicular projected distance n n of these points on the water line EF. This being done, through R and parallel to EF draw RT=a fourth proportional to the whole area MMCD, either triangle MXE or MXF, and the distance nn; through 'T, and at right angles to RT or EF, draw 'I'S meeting the vertical axis of the veffel in S the metacentre; also through the points G, B, and parallel to ST, draw NGW and BV; moreover through S, and parallel to EF, draw WSV, meeting the two former in V and W; then SW is as the flability of the velfel, which will be positive, nothing, or negative, according as the point S is above, coincident with, or below, the point G. If now we suppose W to represent the weight of the whole veffel and burden (which will be equal to the fection MMCD multiplied by the length of the vessel), and P to represent the required weight applied at the gunwale B to fustain the vessel at the given angle of inclination; we shall always have this proportion: as VS: SW:: W: P; which proportion is general, whether SW be positive or negative; it must only in the latter case be supposed to act upward to prevent an overturn.

" In the rectangular vessel, of given weight and dimenfrons, the whole process is so evident, that any farther explanation would be unnecessary. In the trapezoidal veffel, after having found the points G and R, let AD, BC be produced until they meet in K. Then, fince the two fections MMCD, EFDC are equal, the two triangles MMK, EFK are also equal; and therefore the rectangle EK × KF = KM × KM = KM2; and fince the angle of inclination is supposed to be known, the angles at E and F are given. Consequently, if a mean proportional be found between the fines of the angles at E and F, we shall have the following propor-

"As the mean proportional thus found: fine LE:: KM: KF, and as the faid mean proportional: fine LF:: KM: KE; therefore ME, MF become known: from whence the area of either triangle MXE or MXF, the distance nn, and all the other requisites, may be

"In the mixtilineal fection, let AB = 9 feet = 108 inches, the whole depth = 6 feet = 72 inches, and the altitude of MM the line of floatation 4 feet or 48 inches; also let the two curvelinear parts be circular

quadrants of two feet, or 24 inches radius each. Then Fl ating the area of the two quadrants = 9:4:7808 fquare inches, and the diffance of their centres of gravity from the bottom = 13.8177 inches very nearly; also the area of the included rectangle atie = 1440 square inches, and the altitude of its centre of gravity 12 inches; in like manner, the area of the rectangle AB cd will be found = 5184 square inches, and the altitude of its centre of gravity 48 inches: therefore we shall have

"Now the fum of the momenta, divided by the fum of the areas, will give $\frac{278613.98966016}{7528.7808} = 37.006$ inches, the altitude of G, the centre of gravity of the fection ABCD above the bottom. In like manner, the altitude of R, the centre of gravity of the section MMCD, will be found to be equal 123093.98966016

= 24.934 inches; and confequently their difference, or the value of GR = 12.072 inches, will be found.

Suppose the veffel to heel 15°, and we thall have the following proportion; namely, As radius: tangent of 15°:: MX = 54 inches: 14.469 inches = ME or MF; and consequently the area of either triangle MXE or MXF = 390.663 square inches. Therefore, by theorem 4th, as $4936.7808:390.663::72 = nn = \frac{2}{3}$ AB: 5.6975 inches = RT; and, again, as radius: fine of $15^{\circ}::12.072 = GR:3.1245$ inches = RN; confequently RT - RN = 5.6975 - 3.1245 = 2.573inches = SW, the stability required.

"Moreover, as the fine of 15°: radius :: 5.5975 = RT: 22.013 = RS, to which, if we add 24.934, the altitude of the point R, we shall have 46.947 for the height of the metacentre, which taken from 72, the whole altitude, there remains 25.053; from which, and the half width = 54 inches, the distance BS is found = 59.529 inches very nearly, and the angle SBV = $80^{\circ} - 6' - 42''$; from whence SV = 58.645 inches.

Again: Let us suppose the mean length of the vessel to be 40 feet, or 480 inches, and we shall have the weight of the whole vessel equal to the area of the section MMCD = 4936.7808 multiplied by 480 = 2369654.784 cubic inches of water, which weighs exactly 85708 pounds avoirdupoife, allowing the cubic foot to weigh 62.5 pounds

"And, finally, as SV : SW (i.e.) as 58.645 : 2.573 :: 8:708:3760 +, the weight on the gnnwale which will fustain the vessel at the given inclination. Therefore a veffel of the above dimentions, and weighing 38 tons, 5 cwts. 28 lbs. will require a weight of 1 ton,

13 cwts. 64 lbs. to make her incline 150.

"In this example, the deflecting power has been fupposed to act perpendicularly on the gunwale at B; but if the veffel is navigated by fails, the centre velique must be found; with which, and the angle of deflection, the projected distance thereof on the line SV may be obtained; and then the power, calculated as above,

Fluent || Fordyce.

necessary to be applied at the projected point, will be that part of the wind's force which causes the vessel to heel. And conversely, if the weight and dimensions of the vessel, the area and altitude of the sails, the direction and velocity of the wind be given, the angle of

deflection may be found."

FLUENT, or FLOWING QUANTITY, in the doctrine of fluxions, is the variable quantity which is confidered as increasing and decreasing; or the fluent of a given fluxion, is that quantity whose fluxion being taken, according to the rules of that doctrine, shall be the same with the given fluxion. See FLUXIONS. Encycl.

FLUIDS, MOTION IN. See HYDROSTATICS and RESISTANCE OF FLUIDS Encycl. and MOTION in this

Subblement.

FOGEDAR, the military governor of a fubordinate diffrict in India, who has fometimes the addition-

al office of collecting the revenues.

FOLIATE, a name given by some to a curve of the 2d order, expressed by the equation $x^3 + y^3 = axy$, being one species of desective hyperbolas, with one asymptote, and consisting of two infinite legs crossing each other, forming a fort of leaf. It is the 42d species of Newton's Lines of the 3d Order.

FORCER, in Mechanics, is properly a piston without a valve. For, by drawing up such a piston, the air is drawn up, and the water follows; then pushing the piston down again, the water, being prevented from descending by the lower valve, is forced up to any height above, by means of a side branch between the

two.

FORDYCE (James, D.D.) fo well known to ferious readers by his fermons to young women and other specimens of pulpit eloquence, was born at Aberdeen in the year 1720. His father was a man much efteemed, and held, more than once, the office of chief magistrate in his native city; and his mother was a woman of good sense, amiable temper, and exemplary piety. This respectable pair had the singular felicity of transmitting superior talents to almost every individual of a numerous family; of one of which, viz. David Fordyce, the reader will find some account in the En-

cyclopædia.

The subject of this memoir, who was their fourth fon, acquired, as well as his brother, the rudiments of claffical learning at the grammar school of Aberdeen, whence he was removed to the Marischal college and university in the same city. Having completed a regular course of study both in philosophy and theology, he was licensed, when very young, according to the forms of the church of Scotland, to be a preacher of the gospel; and was soon afterwards preferred to the place of fecond minister in the collegiate church of Brechin in the county of Angus. After remaining there for some years, he received a presentation to the church of Alloa near Stirling; and though the inhabitants of that parish were prepossessed in favour of another minister whom they knew, and prejudiced against Mr Fordyce whom they did not know; fo narrow minded and totally deftitute of tafte was his colleague in Brechin, that he judged it expedient to hazard the consequences of a removal. He was aware that he entered on his new charge under a confiderable degree of popular odium; but he thought it more probable that he should be able to overcome that odium, than Ford conciliate the affections of a four fanatic. In this expectation he was not deceived. The prejudices of the good people in Alloa were very quickly removed, not more by the able and impressive manner in which he conducted the public services of the Lord's day, than by the amiable and condescending spirit with which he performed the more private duties of visiting and catechising in the different districts of his parish; duties which, as they were wont to be performed by the Scotch clergy, contributed much more than preaching to the religious instruction of the lower classes of the people.

It was during his refidence at Alloa that Mr Fordyce first distinguished himself as an author by the successive publication of the three following fermons. The first, upon the eloquence of the pulpit, was annexed to "the Art of Preaching" by his brother David; the second, upon the methods of promoting edification by public institutions, was preached at the ordination of the Rev. Mr Gibson minister of St Ninian's, a neighbouring parish, in the year 1754, and published, with the charge and notes, in 1755; and the third, upon the de-lusive and perfecuting spirit of popery, was preached the same year before the synod of Stirling and Perth; and being published, came very quickly to a second edition. But the fermon which most strongly arrested the attention, both of the audience before which it was delivered, and of the public to which, in 1760, it was given from the prefs, was that on the folly, infamy, and mifery of unlawful pleasure, preached before the Gene ral Affembly of the Church of Scotland. The choice of fuch a subject, on such an occasion, excited the surprise of all his hearers, and tempted the younger part of them to smile at the very reading of the text; but this unseasonable mirth was soon converted into seriousness. The picture exhibited in this fermon is the work of a mafter; and we have been affured by a friend who heard it preached, that the spirit and elegance of the composition was so seconded by the solemnity and animation with which it was delivered, that it made a very striking impression, not only upon the more respectable part of the audience, but upon minds of noted levity: It raised indeed its writer's fame as a pulpit orator to an unrivalled eminence among his brethren in Scotland.

About this time, and we believe in confequence of this fermon, Mr Fordyce received from the university of Glasgow a diploma, creating him Doctor in Divinity; and if there is yet any thing honourable in academical degrees, prostituted as they have long been by an undistinguishing distribution, the honour could not have been conferred with greater propriety on any man in the cluurch to which he then belonged.

In that church he did not long remain. Soon after the publication of this fingular fermon, and his confequent acquisition of academical honours, he accepted of an invitation from a fociety of Protestant distenters, who had their place of meeting in Monkwell-street, London, to become colleague and successor to their pastor, who was then old and infirm, and who died indeed in the space of a few months. This gave occasion to the Doctor to display his oratory once more both from the pulpit and the press in a fermon on the death of Dr Lawrence. He was now sole pastor to

Fyce. the congregation of Monkwell-street; and preached for many years, with great powers of eloquence and fervor of piety, to an audience always crowded and often over-

When a preacher obtains, with or without merit, an uncommon share of popularity, a considerable proportion of his hearers will ever confift of those, who are guided in their choice rather by curiofity and fashion, than by found judgment. The attachments of fuch people are as capricious and variable as their minds; and they change their preacher as they change their dress, not from their own taste, for in general they have none; but from the defire of being where others are, of doing what others do, and of admiring what others admire. Dr Fordyce appreciated justly the value of fuch mens approbation, and knew it eventually by experience; but he was more than compenfated for the lofs of hearers of this description by the fleady adherence of others, whose effect was most desirable, because it was grounded upon the dictates of a found understanding.

At latt, about Christmas 1782, when his health, which had long been declining, rendered it necessary, in his own opinion, and in the opinion of his physicians, to discontinue his public services, he refigned his charge in Monkwell-street, and retired to a villa in Hampshire, in the neighbourhood of the Earl of Bute, who honoured him with his friendship, and to whose valuable library he had free access. Afterwards he removed to Bath, where having, with Christian patience, suffered much from an afthmatic complaint, to which he had been subject for some years, on the 1st of October

1796 he expired without a groan.

Were we to hazard an opinion of Dr Fordyce's intellectual powers from fuch a perufal of his works as we must acknowledge to have been hasty, we would say that he was a man of genius rather than of judgment; that his imagination was the predominant faculty of his mind; and that he was better fitted, by an address to the passions, to enforce the practice of virtue, than, by the exertions of his own understanding, to vindicate speculative truth, or to detect the fophiltry of error. From this remark, we cannot be suspected of a wish to lessen his character in the public esteem; for his talents, as they appear to us, are furely of more value to a preacher than those which are perhaps better adapted to literary or scientific pursuits. In none of his works indeed do we perceive any evidence either of profound science, or of various erudition; though we doubt not but those works are every thing which their author intended them to be. Of his fermons to young women, which have attracted most general notice, it would be prefumptuous in us to give a character; for though we fat down many years ago to read them, we could not get through; and we have never made a fecond attempt. As far as we can depend upon what we recollect of these far-famed discourses, the censure passed on them by Mrs Wolstoncraft seems to be just. Their author, however, was certainly qualified to excel, and actually did excel as a preacher. We have already men-

tioned with approbation three or four of his occasional Fordyce, fermons; but perhaps the finest specimen of pulpit ora- Formula. tory which ever fell from his pen, is the charge which he delivered at the ordination of his successor in the meeting of Monkwell-street. It is indeed one of the most valuable discourses of the kind that we have seen, and should be read with attention by every clergyman of every denomination, who wishes to discharge his duty with credit to himself and with advantage to his

The effect of Dr Fordyce's addresses from the pulpit was much heightened, not only by an action and an elocution, which he studied with care and practised with success; but by the figure of his person, which was peculiarly dignified, and by the expression of his countenance, which was animated at all times, but animated most of all when lighted up by the ardor of his foul in the service of God. By some of his hearers, it was observed that, on many occasions, he seemed not merely to fpeak, but to look conviction to the heart. His eye, indeed, was particularly bright and penetrating, and he had carefully attended to the effect which an orator may often produce upon an audience by the judicious use of that little, but invaluable organ.

With respect to his theological sentiments, we are affured (A) they were in no extreme, but liberal, rational, and manly. He feems to have been untainted by that rage of innovation, which of late has fo completely diffigured the creed, as well religious as political, of the great body of English diffenters. The consequence was, that he lived on terms of friendship with men of very opposite fentiments; with Price a republican and Arian, and with Johnson, who, though he hated a whig and a Presbyterian, respected talents and worth

wherever he found them.

We shall conclude this short sketch of Dr Fordyce's life and character with the following lift of his works, of which some have been translated into several languages. 1. A Sermon and Charge, at the ordination of the Rev. Mr Gibson Minister of St Ninian's, 1754. 2. Another Ordination Sermon on the Eloquence of the Pulpit, annexed to his brother's "Art of Preaching," 1754. 3. A Sermon on the Spirit of Popery, 1754. 4. A Sermon on the Folly, Infamy, and Mifery of Unlawful Pleasure, 1760. 5. A Sermon on the Death of Dr Lawrence, 1760. 6. Sermons to Young Women, 2 vols. 1765. 7. A Seimon on the Character and Conduct of the Female Sex, 1776. 8. Addresses to young meu, 2 vols. 1777. 9. A Charge at the Ordination of the Rev. James Lindsey, in Monkwell freet, 1783. 10. Addresses to the Deity, 1785. 11. Poems, 1786. 12. A Discourse on Pain, 1791. He also re-published, with an additional character, "The Temple of Virtue, a Dream," written by his brother David his brother David.

FORMULA, a theorem or general rule or expreffion, for resolving certain particular cases of some problem, &c. So $\frac{1}{2}s + \frac{1}{2}d$ is a general formula for the greater of two quantities whose sum is s and difference d; and $\frac{1}{2}s - \frac{1}{2}d$ is the formula, or general value, for

Forker. the less quantity. Also $\sqrt{dx-x^2}$ is the formula, or friends his talents had acquired him, and involved him. Forder general value, of the ordinate to a circle, whose diameter is d, and abfails κ .

FORSTER (John Reinhold, LL.D.) professor of natural history in the university of Halle, member of the academy of sciences at Berlin, and of other learned societies, was born at Dirschau, in West Prussia, in the month of October 1729, and was formerly a Protestant clergyman at Dantzick. He had a numerous family, and the emoluments of his office were slender. He therefore quitted Dantzick, and went, first to Ruffia, and thence to England, in quest of a better settlement than his own country afforded. In the diffenting academy at Warrington he was appointed tutor in the modern languages, with the occasional office of lecturing in various branches of natural history. For the first department he was by no means well qualified; his extraordinary knowledge of languages, ancient and modern, being unaccompanied by a particle of taste; and his use of them being all barbarous, though fluent. As a natural historian, a critic, geographer, and antiquary, he ranked much higher; but, unfortunately, these were acquisitions of little value in his academical department.

At length he obtained the appointment of naturalith and philosopher (if the word may be so used) to the second voyage of discovery undertaken by Capt. Cook; and from 1772 to 1775 he accompanied that immortal navigator round the world. On his return he refided in London, till the improper conduct of himself and his son made it expedient for them both to leave the kingdom. Fortunately he received an invitation to Halle, where, for 18 years, he was a member of the philosophical and medical faculties. Among his works are: An Introduction to Mineralogy, or, An accurate Classification of Fossils and Minerals, &c. London, 1768, 8vo. A Catalogue of the Animals of North America, with short Directions for collecting, preferving, and transporting all kinds of Natural Curiofities, London, 1771, 8vo. Observations made during a Voyage round the World, on Physical Geography, &c. London, 1778. He was the author of a great many productions in English, Latin, or German, and of feveral papers in the Philosophical Transactions. He translated into English, Bougainville's Voyage round the World, and Kalm's, Bossu's, and Reidsel's Travels. He was employed likewise, when in England, in the Critical Review; and he wrote various detached papers on different subjects, which have been inferted in foreign journals and the transactions of learned academies.

He died at Halle on the 16th of December 1798,

-in the 70th year of his agc.

FORSTER (George), the fon of the preceding, was born at Dantzick, and accompanied his father to England when he was about twelve years of age. He was entered a fludent in the academy at Warrington, and foon acquired a very perfect use of the English tongue. He also diftinguished himself greatly by his attainments in science and literature in general; adding to an excellent memory, quick parts and a fertile imagination. His temper was mild and amiable; in which he much differed from his father, one of the most quarrelsome and irritable of men; by which disposition, joined to a total want of felf and family in perpetual difficulties.

The case was very different with the subject of this memoir; for when Dr Forster was appointed naturalist to captain Cook, his son, through the interest of the friends whom his good nature had made, was affociated with him in his office. The voyage continued during the space of three years; and on their return the two Forfters published jointly a botanical work in Latin, containing the characters of a number of new genera of plants, discovered by them in their circumnavigation. Thus far they acted properly in the service of government for the advancement of science; but in publishing another work their conduct was not proper.

The father had come under an engagement not to publish separately, from the authorised narrative, any account of the voyage; and this engagement he and his fon were determined to violate. An account of the voyage, therefore, was published in English and German by George; and the language, which is correct and elegant, was undoubtedly his; but those who knew both him and his father, are fatisfied that the matter proceeded from the joint stock of their observations and reflections. Several parts of the work, and particularly the claborate investigations relative to the languages spoken by the natives of the South Sea Islands, and the speculations concerning their successfive migrations, are thought to be strongly impressed with the genius of the elder Forster.

That a work thus furreptitiously ushered into the world was not patronifed by those with whom the authors had fo ungratefully broken faith, could excite no wonder, even though the publication itself had been otherwife unexceptionable; but this was far from being the case. It abounds with reflections injurious to the government whose servants they had been, and not just to the navigators employed on voyages of discovery. younger Forster, too, had some time before published a book replete with factious fentiments; and the coldness with which he and his father were both treated in consequence of such conduct, determined them to

leave London.

We have already related all that we know of the father, who was recommended to our notice only by his connection with the illustrious Cook; and of the fon, there is a short account in the Monthly Magazine, by Charles Pougens, fraught with those impious and feditions reflections which so frequently difgrace a mifcellany, which would otherwife be highly valuable. According to this author, George Forster was defirous to fettle in France. Avaricious of glory, and an idolator of liberty, Paris was the city most suitable to his tafte and character of any in Europe. Notwithstanding this, he was soon constrained to leave it: the interest of his family demanded this facrifice; for a lcarned man, who fails round the world, may enrich his memory, but he will not better his fortune. He was accordingly obliged to accept the place of profeffor of natural history in the university of Castel. But his factious spirit accompanied him whithersoever he went. It is well known, that the petty princes of Germany have long been in the practice of hiring out their troops to more opulent fovereigns engaged in war. This practice, which we are not difposed to deprudence in common concerns, he lost almost all the fend, not only scandalized our Cosmopolite, but so ir-

Forster Folil.

Rer. ritated his temper and offended his pride, because, for- honour, as they are certainly the guardians of domestic footh, the Prince of Hesse. Cassel would not by him be persuaded to relinquish it, that he did every thing in his power, we are told, to withdraw himself from a situation fo unfuitable to a thinking being. Every thing in his power! Did the Prince retain him in the university contrary to his inclination? The university of Cassel must be contemptible indeed, if the prelections of fuch a man as George Forster were of such consequence to it.

He got away, however; and the fenate of Poland having offered him a chair in the university of Wilna, Forster accepted of the invitation. But although this office was very lucrative, and the enlightened patriots of that country did not neglect to procure him all the literary fuccours of which he stood in need, he could not be long happy in a femi-barbarous nation, in which liberty was fuffered to expire under the intrigues

of Russia and Prussia.

On this, with wonderful confishency, the man who could not endure the despotism of Hesse, or even the aristocracy of England, accepted of the propositions of that friend to liberty Catharine II; who, jealous of every species of glory, wished to signalize her reign, by procuring to the Ruffian nation the honour of undertaking, after the example of England and France, a new voyage of discovery round the world. Unfortunately for the progress of knowledge, the war with the Ottoman Porte occasioned the miscarriage of this useful

project.

But Forster could not long remain in obscurity. The different publications with which he occasionally enriched natural history and literature, encreased his reputation. The Elector of Mentz accordingly appointed him president of the university of the same name; and he was discharging the functions of his new office when the French troops took poffession of the capital. This philosophical traveller, who had studied fociety under all the various aspects arising from different degrees of civilization; who had viewed man fimple and happy at Otaheite; - an eater of human flesh in New Zealand, corrupted by commerce in England, depraved in France by luxury and atheifm, in Brabant by fuperstition, and in Poland by anarchy; -beheld with wild enthusiasm the dawnings of the French revolution, and was the first, fays M. Pougens, to promulgate republicanism in Germany.

The Mayencois, who had formed themselves into a national convention, fent him to Paris, in order to folicit their reunion with the French republic. But, in the course of his mission, the city of Mentz was befieged and retaken by the Prussian troops. This event occasioned the loss of all his property; and what? was still more disastrous, that of his numerous manuferipts, which fell into the hands of the Prince of Pruf-

fia.

Our biographer, after conducting his hero through these scenes of public life, proceeds to give us a view of his domestic habits and private principles. He tells us, that he formed a connection (whether a marriage or not, the studied ambiguity of his language leaves rather uncertain) with a young woman named Therephy, had divested herself of all the prejudices which, we trust, the ladies of this country still consider as their

SUPPL. VOL. 1. Part II.

peace. Miss Hayne was indignant at the very name of duty. With Eloifa she had taken it into her head,

Love, free as air, at fight of human ties, Spreads his light wings, and in a moment dies.

She was frank enough, however, fays our author, to acknowledge the errors of her imagination; and from this expression, and his calling her afterwards Forster's wife, we are led to suppose that she was actually married to him. But their union, of whatever kind, was of short duration. Though the lady is faid to have been passionately attached to celebrated names, the name of George Forster was not sufficient to satisfy her. He foon ceased, we are informed, to please her; she therefore transferred her affections to another; and, as was very natural for a woman who was indiguant at the name of duty, she proved false to her husband's bed. Forfter, however, pretended to be fuch a friend to the modern rights of men and women, that he defended the character of his Therefa against crowds who condemned her conduct. Nay, we are told, that he confidered himself, and every other husband who ceases to please, as the adulterer of nature. He therefore laboured strenuously to obtain a divorce, to enable Therefa Hayne to espouse the man whom she preferred to himself. Strange, however, to tell, the prejudices even of this Cosmopolite were too strong for his principles. While he was endeavouring to procure the divorce, he made preparations at the same time, by the study of the oriental languages, to undertake a journey to Thibet and Indostan, in order to remove from that part of the world, in which both his heart and his perfon had experienced fo fevere a shock. But the chagrin occafioned by his misfortunes, joined to a scorbutic affection, to which he had been long fubject, and which he had contracted at fea during the voyage of circumnavigation, abridged his life, and prevented him from realifting this double project. He died at Paris, at the age of thirty-nine, on the 13th of February 1792.

This is a strange tale; but we trust it will not prove useless. The latter part of it at least shows, that when men divest themselves of the principles of religion, they foon degenerate from the dignity of philosophers to the level of mere fenfualists; and that the woman who can, in defiance of decorum and honour, transfer her affections and her person from man to man, ranks no higher in the scale of being than a female brute of more than common fagacity. It shews likewise, that the contempt of our modern fages for those partial attachments which unite individuals in one family, is a mere pretence; that the dictates of nature will be heard; and the laws of nature's God obeyed. George Forster, though he was fuch a zealous advocate for liberty and equality, as to vindicate the adultery of his wife; yet felt fo fenfibly the wound which her infidelity inflicted on his honour, that he could not furvive it, but perished, in con-

fequence, in the flower of his age.

ROYAL FORT, is one whose line of defence is at

least 26 fathoms long.

Star FORT, is a sconce or redoubt, constituted by refa Hayne, who, by the illumination of French philoso- entering and faliant angles, having commonly from five to eight points, and the fides flanking each other.

FOSSIL-MEAL, otherwise called bac lune, mineral argaric,

argaric, and guhr, is, according to M. Fabbroni, a mixed earth, which exhales an argillaceous odour, and throws out a light whitish smoke when sprinkled with water. It is abundant in Tufcany, where it is employed for cleaning plate. It does not effervesce with acids: is infufible in the fire, in which it lofes an eighth part of its weight, though it becomes scarcely diminished in bulk; and, according to the analysis made by M. Fabbroni, confifts of the following component parts: filiceous earth 55, magnefia 15, water 14, argil 12, lime 3, iron 1. With this earth, which is found near Casteldelpiano in the territories of Sienna, M. Fabbroni composed bricks, which, either baked or unbaked, floated in water. Hence he infers, that the floating bricks, which Pliny mentions as peculiar to Massilua and Calento, two cities in Spain, must have been made of fossil meal. Bricks made of that substance resist water exceedingly well, and unite perfectly with lime; they are subject to no alteration either by heat or cold; and about a twentieth part of argil may be added with advantage to their composition, without depriving them of the property of floating. M. Fabbroni tried their relistance, and found it very little inferior to that of common bricks; but it is much greater in proportion to their lightness. One of these bricks, seven inches in length, four and a half in breadth, and one inch eight lines in thickness, weighed only 14th ounces; whereas a common brick weighed 5 pounds 63ths

Bricks of fosiil-meal may be of important benefit in the construction of reverberating furnaces; as they are fuch bad conductors of heat, that a person may bring one half of them to a red heat, while the other is held in the hand. They may be employed also for buildings that require to be light; for constructing cooking places on board ships; and also floating batteries, the parapets of which, if made of these bricks, would be proof against red hot bullets; and, lastly, for constructing

powder magazines.

FOULAHS or FOOLAHS, a people in Africa, inhabiting a country on the confines of the great defert (fee SAHARA in this Suppl.) along the parallel of nine degrees north. They partake much of the negro form and complexion; but have neither the jetty colour, thick lips, nor crisped hair of the negroes. They have also a language distinct from the Mandinga, which is the prevailing one in this quarter. The Foulahs occupy, at least as sovereigns, several provinces or kingdoms, interspersed throughout the tract comprehended between the mountainous border of the country of Sierra Leona on the west, and that of Tombuctoo on the east; as also a large tract on the lower part of the Senegal river; and these provinces are insulated from each other in a very remarkable manner. Their religion is Mahomedanism; but with a great mixture of Paganism, and with less intolerance than is practised by the Moors.

The principal of the Foulah states is that within Sierra Leona; and of which Teemboo is the capital. The next in order appears to be that bordering on the fouth of the Senegal river, and on the Jaloffs; this is properly named Siratik. Others of less note are Bondou, with Foota-Torra adjacent to it, lying between the rivers Gambia and Falemé; Foola-doo and Brooko along the upper part of the Senegal river; Wassela be-

down on the same river, and joining to Tombuctoo on Fouli the west.

The kingdom of the Foulahs, fitnated between the upper part of the Gambia river and the coast of Sierra Leona, and along the Rio Grande, is governed by a Mahometan fovereign; but the bulk of the people appear to be Pagans. From the circumstances of their long hair, their lips, and comparatively light colour, Major Rennel is decidedly of opinion, that the Foulahs are the Leucæthiops of Ptolemy and Pliny. The former, as he observes, places the Leucæthiops in the fituation occupied by the Foulahs; and by the name which he gave them, he evidently meant to describe a people less black than the generality of the Ethiopians. Hence it may be gathered, that this nation had been traded with, and that some notices respecting it had been communicated to Ptolemy. It may also be re-marked, that the navigation of Hanno terminated on this coast; and as this was also the term of Ptolemy's knowledge, it may justly be suspected, that this part of the coast was described from Carthaginian materials.

Those who have perused the Journal of Messrs Watt and Winterbottom through the Foulah country in 1794, and recollect how flattering a picture they give of the urbanity and hospitality of the Foulahs, will be gratified on finding that this nation was known and distinguished from the rest of the Ethiopians at a re-

mote period of antiquity.

The contrast between the Moorish and Negro characters is as great as that between the nature of their respective countries, or between their form and complexion. The Moors appear to possess the vices of the Arabs without their virtues; and to avail themselves of an intolerant religion, to oppress strangers: whilst the Negroes, and especially the Mandingas, unable to comprehend a doctrine that substitutes opinion or belief for the focial duties, are content to remain in their humble state of ignorance. The hospitality shewn by these good people to Mr Park, a destitute and forlorn stranger, raifes them very high in the scale of humanity: and I know of no fitter title, fays Mr Rennel, to confer on them than that of the Hindoos of Africa; at the fame time, by no means intending to degrade the Mahomedans of India by a comparison with the African Moois. - See Major Rennel's Geographical Illustrations of Mr Park's Journey, and of North Africa at large, printed for the African Affociation.

FRANCAIS (PORT DES), the name given by Perouse to a bay, or rather harbour, which he undoubtedly discovered on the north-west coast of America. It is fituated, according to him, in 58° 37' N. Lat. and in 130° 50' W. Long. from Paris. When the two frigates which he commanded approached it, as they were stretching along the coast from fouth to north, he perceived from his ship a great reef of rocke, behind which the fea was very calm. This reef appeared to be about three or four hundred toifes in length from east to west, and to be terminated, at about two cables length, by the point of the continent, leaving a pretty large opening; so that Nature seemed to have made, at the extremity of America, a harbour like that of 'Toulon, only more vast in her defigns and in her means: this new harbour was three or four leagues deep.

Some officers, who had been dispatched in boats to youd the upper part of the Niger; and Massina lower reconneitre this harbour, gave a report of it extremely favourable;

p mis favourable; and on the 3d of July 1786, the two frigates entered it, and anchored near its mouth in three fathoms and a half, rocky bottom. The bay, however, was quickly founded, and much better anchoring ground discovered at an island in the middle of it, where the ships might ride in 20 fathoms water with muddy bottom. This ground was taken possession of, an observatory erected on the island, which was only a musket shot from the ships, and a settlement formed for their flay in the harbour. From a report made by one of the officers who had penetrated towards the bottom of the bay, Perouse had conceived the idea of finding perhaps a channel by which he might proceed into the interior of America; but he was disappointed. The bottom of the bay, indeed, according to him, is one of the most extraordinary places in the world. It is a bason of water, of a depth in the middle that could not be fathomed, bordered by peaked mountains of an exceffive height, covered with fnow, without a blade of grass upon this immense collection of rocks, condemned by Nature to perpetual sterility. "I never (fays he) faw a breath of air ruffle the furface of this water; it is never troubled but by the fall of enormous pieces of ice, which continually detach themselves from five different glaciers, and which in falling make a noise that resounds far in the mountains. The air is in this place so very calm, and the filence fo profound, that the mere voice of a man may be heard half a league off, as well as the noise of some sea birds which lay their eggs in the cavities of thefe rocks."

It was at the extremity of this bay that he was in hopes of finding a passage into the interior of America. He imagined that it might terminate in a great river, of which the course might lie between two mountains; and that this river might take its fource in the great lakes to the northward of Canada. Two channels were indeed found, firetching, the one to the east, and the other to the west; but both were very soon termi-

nated by immense glaciers.

In Port des Français the variation of the compass is 28° east, and the dip of the needle 74°. The sea rises there seven feet and a half at full and change of the moon, when it is high water at one o'clock. fea breezes, or perhaps other causes, act so powerfully upon the current of the channel, that M. Perouse faw the flood come in there like the most rapid river; while, in other circumstances, at the same period of the moon, it may be stemmed by a boat. In this channel he lost two shallops and twenty men. In his different excurfions, he found the high water mark to be about 15 feet above the furface of the fea. These tides are probably incident to the bad feafon. When the winds blow with violence from the fouthward, the channel must be impracticable, and at all times the currents render the entrance difficult; the going out of it also requires a combination of circumstances, which may retard the departure of a veffel many weeks; there is no getting un- raspberries, and strawberries; clusters of elder trees, the

advantage of the morning tide; finally, the eafterly Francais. winds, which are contrary, appeared to him to be more frequent than those from the west, and the vast height of the furrounding mountains never permits the land breezes, or those from the north, to penetrate into the

As this port possesses great advantages, M. Perouse thought it a duty incumbent on him to make its inconveniences also known. It seemed to him that this anchorage is not convenient for those ships which are fent out at a venture for trafficking in skins; such ships ought to anchor in a great many bays, and always make the shortest stay possible in any of them; because the Indians have always disposed of their whole stock in the first week, and all lost time is prejudicial to the interests of the owners: but a nation which should form the project of establishing factories similar to those of the English in Hudson's Bay, could not make choice of a place more proper for such a settlement. A simple battery of four heavy cannon, placed upon the point of the continent, would be fully adequate to the defence of so narrow an entrance, which is also made so difficult by the currents. This battery could not be turned or taken by land, because the sea always breaks with such violence upon the coast, that to disembark is impossible. The fort, the magazines, and all the fettlements for commerce, should be raised upon Cenotaph Island (A), the circumference of which is nearly a league: it is capable of being cultivated, and there is plenty of wood and water. The ships not having their cargo to feek, but being certain of having it collected to a fingle point, would not be exposed to any delay: some buoys, placed for the internal navigation of the bay, would make it extremely safe and easy. The settlement would form pilots, who, better versed than we are in the set and strength of the current at particular times of tide, would ensure the entrance and departure of the ships. Finally, continues the author, our traffic for otters skins has been so very considerable, that I may fairly presume there could not, in any part of America, be a greater quantity of them collected.

The climate of this coast seemed to Perouse much milder than that of Hudson's Bay in the same latitude. Pines were measured of fix feet diameter, and 140 high; while those of the same species at Prince of Wales's Fort and Fort York are of a dimension scarce sufficient for fludding fail-booms. Vegetation is also very vigorous during three or four months of the year; and our author thinks, that Russian corn, as well as many common plants, might thrive exceedingly at Port des Français, where was found great abundance of celery, lupine, the wild pea, yarrow, and andive. Among these pot herbs were feen almost all those of the meadows and mountains of France; fuch as the angelica, the butter cup, the violet, and many species of grass proper for fodder. The woods abound in goofeberries, der way but at the top of high water; the breeze from dwarf willow, different species of briar which grow in the west to the north-west does not often rise till to- the shade, the gum poplar tree, the poplar, the sallow, ward eleven o'clock, which does not permit the taking the horn-beam; and, finally, superb pines, fit for the 4 P 2

(A) This name was given to the island in the bay from the monument erected on it to the memory of their unfortunate companions.

Francais. masts of our largest ships. Not any of the vegetable productions of this country are unknown in Europe. M. de Martinière, in his different excursions, met with only three plants which he thought new; and it is well known, that a botanist might do the same in the vicinity of Paris.

The rivers were filled with trout and falmon; and as the Indians fold these fish to the French in greater quantities than they could confume, they had very little fishing in the bay, and that only with the line. They caught fome ling, a fingle thornback, fome plaice, fletans or failans, of which some were more than 100 pounds in weight (B), and a fish refembling the whiting, but a little larger, which abounds on the coast of Provence, where it is known by the name of poor-prieft. Perouse calls these fish capelans. In the woods they met with bears, martens, and squirrels; but they saw no great variety of birds, though the individuals were

very numerous.

"If the animal and vegetable productions of this country relemble those of a great many others, its appearance (fays our author) can be compared to nothing. The views which it prefents are more frightful than those of the Alps and the Pyrenees; but at the fame time fo picturefque, that they would deferve the vifits of the curious, were they not at the extremity of the world. The primitive mountains of granite or schistus, perpetually covered with snow, upon which are neither trees nor plants, have their foundation in the sea, and form upon the shore a kind of quay; their slope is so rapid, that after the first two or three hundred toifes, the wild goats cannot climb them; and all the gullies which feparate them are immense glaciers, of which the tops cannot be discerned, while the base is washed by the sea. At a cable's length from the land there is no bottom at less than 160 fathoms. The fides of the harbour are formed by fecondary mountains, the elevation of which does not exceed from 800 to 900 toifes; they are covered with pines, and overforead with verdure, and the fnow is only feen on their fummits: they appeared to be entirely formed of fchiftus, which is in the commencement of a state of decomposition; they are extremely difficult to climb, but not altogether inaccessible.

"Nature affigns inhabitants to fo frightful a country, who as widely differ from the people of civilized countries as the scene which has just been described differs from our cultivated plains; as rude and barbarous as their foil is rocky and barren, they inhabit this land only to destroy its population: at war with all the animals, they despife the vegetable substances which grow around them. I have feen (fays our author) women and children eat some raspberries and strawberries; but these are undoubtedly viands far too insipid for men, who live upon the earth like vultures in the air, or

wolves and tigers in the forests.

"Their arts are somewhat advanced, and in this respect civilization has made confiderable progress; but that which foftens their ferocity, and polishes their manners, is yet in its infancy. The mode of life they

continually agitated by fear or revenge; prone to an- Franci ger, and easily irritated, they are continually attacking each other dagger in hand. Exposed in the winter to perish for want, because the chase cannot be successful, they live during the fummer in the greatest abundance, as they can catch in less than an hour a fufficient quantity of fish for the support of their family; they remain idle during the rest of the day, which they pass at play, to which they are as much addicted as some of the inhabitants in our great cities. This gaming is the great fource of their quarrels. If to all these defructive vices they should unfortunately add a knowledge of the use of any inebriating liquor, M. Perouse does not hefitate to pronounce, that this colony would be entirely annihilated."

Like all other favages, they are incorrigible thieves; and when they affumed a mild and placid appearance, the Frenchmen were fure that they had stolen something. Iron, of which they appeared to know the use, and of course the value, most excited their cupidity; and when our navigators were engaged in careffing a child, the father was fure to feize the opportunity of taking up, and concealing under his skin-garment, every thing of that metal which lay within his reach, and was

not too heavy to be carried off.

M. Rollin, furgeon major of one of the frigates, thus describes these people. "They have very little similarity to the Californians; they are taller, stouter, of a more agreeable figure, and greater vivacity of expreffion: they are also much their superiors in courage and fense. They have rather a low forehead, but more open than that of the Southern Americans; their eyes are black and very animated; their eyehrows much fuller; their nose of the usual fize, and well formed, except being a little widened at the extremity; their lips thinner; their mouth moderately large; their teeth fine and very even; their chin and ears very regular.

"The women also have an equal advantage over those of the preceding tribes; they have much more mildness in their features, and grace in their limbs .-Their countenance would be even very agreeable, if, in order to set it off, they did not make use of a strange custom of wearing in the lower lip an elliptical piece of wood, lightly grooved on its circumference and both its fides, and which is commonly half an inch thick,

two in diameter, and three in length.

"This fingular ornament, besides being a great deformity, is the cause of a very troublesome as well as dis-gusting involuntary flow of saliva. This appendage is peculiar to the women; and female children are made to undergo the preparatory operations from the time of their birth. For this purpose, the lower lip is pierced with a kind of pin of copper or gold, which is either left in the opening, or its place supplied with a ring of the same material, till the period of puberty. The aperture is then gradually enlarged, by fubstituting first a fmall piece of wood of the form mentioned above, then a larger one; and fo on, increasing its fize by degrees till it reaches the dimensions just stated.

"This extraordinary custom shows the great power purfue excluding all kind of fubordination, they are of dilatation in the lip, and may encourage medical prac-

⁽B) This is a flat fish, longer and not so square as the turbet. Its back is covered with small scales; and those which are taken in Europe are much less than the fletans of Port des Français.

licais titioners in their attempts to remedy deformities of this

part by the use of the knife.

"The general colour of these people is olive, a fainter tinge of which is apparent in their nails, which they fuffer to grow very long; the hue of the skin, however, varies in different individuals, and in various parts of the fame individual, according to their exposure to the action of the air and fun.

"Their hair is, in general, neither so coarse nor black as that of the South Americans. Chefnut coloured hair is by no means unfrequent among them. Their beard is also fuller, and their armpits and parts of sex

better provided with hair.

"The perfect evenness of their teeth led me at first to suspect that it was the effect of art; but after an attentive and minute examination, I could perceive no wearing away of the enamel, and I faw that this regularity is natural. They tattoo and paint their face and body, and bore their ears and the cartilage of their nofe.
"Some writers have imagined, that the custom of

painting the face and body, fo generally adopted by the Africans, Americans, and West Indians, is only intended as a preservative against noxious insects. think, however, that I am warranted in afferting its fole end to be ornament. I found it to prevail among the inhabitants of Easter Island and the natives of Port des Français, without observing among them either venomous insects or reptiles. Besides, I remarked, that they wore paint only when they paid us a vifit; for they made no use of it when in their own houses."

M. Perouse himself speaks not so favourably of the women as M. Rollin. "They are (he fays) the most difgusting of any on the earth, covered with stinking skins, which are frequently untanned; and yet they failed not to excite defires in some persons, in fact of no small consequence: they at first stated many diffi-culties, giving assurances by their gestures that they ran the risk of their lives; but being overcome by pre-fents, they had no objection to the sun being a witness, and absolutely refused to retire into the wood." There can be no doubt that this planet is the god of these people, fince they frequently addressed themselves to it in their prayers; but our voyagers faw neither temple nor priest, nor the least trace of public worship at stated times. They burn their dead.

FRE'GATES FRANÇAISE Basse de, the name given by La Perouse to a dangerous reef of sunken rocks which he discovered in the Pacific ocean. On the north-west extremity of this reef they perceived an islet or split rock from 20 to 25 fathoms in height and about 50 toises in diameter. From this islet the reef extends more than four leagues to the fouth east; and upon the extremity of the point in that direction, the frigates had almost struck before the breakers were obferved. This was during a fine clear night and fmooth fea. With great propriety, the Commodore returned in the morning to ascertain the geographical fituation of this unknown rock; and he estimated the islet to be in 23° 45' N. Lat. and 168° 10' W. Long. from Paris.

FRICTION, in mechanics, is a fubject of great importance both to the practical engineer and to the speculative philosopher. It is therefore our duty to correct, in this Supplement, the mistakes into which we fell when treating of that subject in the Encyclopadia. What we have there taught of friction (fee MECHA- certainty, each descent was repeated eight or ten times;

NICS Sect. II. § 8.) is taken from Ferguson; but it Friction. has been shewn by Mr Vince, that the experiments from which his conclusions were drawn were not properly instituted. That eminent mathematician and philosopher therefore entered upon the investigation of the fubject anew, and endeavoured, by a fet of experiments, to determine the following questions:

1. Whether friction be a uniformly retarding force?

2. The quantity of friction?

3. Whether the friction varies in proportion to the preffure or weight?

4. Whether the friction be the same on whichever

of its furfaces a body moves?

1. With respect to the first of these questions, the author truly observes, that if friction be a uniform force, the difference between it and the given force of the moving power employed to overcome it must also be uniform; and that therefore the moving power, if it be a body descending by its own weight, must descend with a uniformly accelerated velocity, just as when there was no friction. The spaces described from the beginning of the motion will indeed be diminished in any given time on account of the friction; but still they must be to each other as the squares of the times employed. See DYNAMICS in this Supplement.

2. A plane was therefore adjusted parallel to the liorizon, at the extremity of which was placed a pulley, which could be elevated or depressed, in order to render the string which connected the body and the moving force parallel to the plane. A scale accurately divided was placed by the fide of the pulley perpendicular to the horizon, by the fide of which the moving force defcended; upon the scale was placed a moveable stage, which could be adjusted to the space through which the moving force descended in any given time; which time was measured by a well-regulated pendulum clock vibrating feconds. Every thing being thus prepared, the following experiments were made to afcertain the

law of friction.

3. Exp. 1. A body was placed upon the horizontal plane, and a moving force applied, which, from repeated trials, was found to descend 521 inches in 4"; for by the beat of the clock, and the found of the moving force when it arrived at the stage, the space could be very accurately adjusted to the time: The stage was then removed to that point to which the moving force would descend in 3", upon supposition, that the spaces described by the moving power were as the squares of the times; and the space was found to agree very accurately with the time: the stage was then removed to that point to which the moving force ought to defcend in 2", upon the same supposition, and the descent was found to agree exactly with the time: laftly, the stage was adjusted to that point to which the moving force ought to descend in 1", upon the same supposition, and the space was observed to agree with the time. Now, in order to find whether a difference in the time of descent could be observed by removing the ftage a little above and below the positions which corresponded to the above times, the experiment was tried, and the descent was always found too soon in the former, and too late in the latter case; by which the author was affured, that the spaces first mentioned corresponded exactly to the times. And, for the greater Friction. and every caution used in this experiment was also made use of in all the following.

> Exp. 2. A second body was laid upon the horizontal plane, and a moving force applied which descended 413 inches in 3"; the stage was then adjusted to the space corresponding to 2", upon supposition that the spaces descended through were as the squares of the times, and it was found to agree accurately with the time; the stage was then adjusted to the space corresponding to I", upon the same supposition, and it was found to agree with the time.

> Exp. 3. A third body was laid upon the horizontal plane, and a moving force applied, which descended 595 inches in 4"; the stage was then adjusted to the space corresponding to 3", upon supposition that the spaces descended through were as the squares of the times, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 2", upon the same supposition, and it was found to agree with the time; the stage was then adjusted to the space correfponding to 1", and was found to agree with the time.

Exp. 4. A fourth body was then taken and laid upon the horizontal plane, and a moving force applied, which descended 55 inches in 4"; the stage was then adjusted to the space through which it ought to descend in 3", upon supposition that the spaces descended through were as the squares of the times, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 2", upon the same supposition, and was found to agree with the time; laftly, the flage was adjusted to the space corresponding to 1", and it was found to agree exactly with the time.

Besides these experiments, a great number of others were made with hard bodies, or those whose parts so firmly cohered as not to be moved inter se by the friction; and, in each experiment, bodies of very different degrees of friction were chosen, and the results all agreed with those related above; we may therefore conclude, that the friction of hard bodies in motion is a uniformly retarding force.

But to determine whether the same was true for bodies when covered with cloth, woollen, &c. experiments were made in order to ascertain it; when it was found, in all cases, that the retarding force increased with the velocity; but, upon covering bodies with paper, the consequences were found to agree with those related

4. Having proved that the retarding force of all hard bodies arising from friction is uniform, the quantity of friction, considered as equivalent to a weight without inertia drawing the body on the horizontal plane backwards, or acting contrary to the moving force, may be immediately deduced from the foregoing experiments. For let M = the moving force expressed by its weight; F = the friction; W = the weight of the body upon the horizontal plane; S = the space through which the moving force descended in the time t expressed in feconds; $r = 16 \frac{1}{12}$ feet; then the whole accelerative force (the force of gravity being unity) will be $\frac{M}{M+W}$ hence, by the laws of uniformly accelerated motions, $\frac{M - F}{M + W} \times rt^2 = S, \text{ consequently } F = M - \frac{M \times W \times S}{rt^2}$ To exemplify this, let us take the case of the last experiment, where M = 7, W = 25 1, 5 = 47 feet, Price t = 4''; hence $F = 7 - \frac{32\frac{1}{4} \times 4\frac{7}{15}}{16\frac{7}{15} \times 16} = 6.417$; con-

fequently the friction was to the weight of the rubbing body as 6.4167 to 25.75. And the great accuracy of determining the friction by this method is manifest from hence, that if an error of 1 inch had been made in the descent (and experiments carefully made may always determine the space to a much greater exactness), it would not have affected the conclusion obodth part of the whole.

5. We come in the next place to determine, whether friction, cateris paribus, varies in proportion to the weight or pressure. Now if the whole quantity of the friction of a body, measured by a weight without inertia equivalent to the friction drawing the body backwards, increases in proportion to its weight, it is manifest, that the retardation of the velocity of the body ariting from the friction will not be altered; for the re-Quantity of friction

tardation varies as Quantity of matter; hence, if a body be put in motion upon the horizontal plane by any moving force, if both the weight of the body and the moving force be increased in the same ratio, the acceleration arifing from that moving force will remain the same, because the accelerative force varies as the moving force divided by the whole quantity of matter, and both are increased in the same ratio; and if the quantity of friction increases also as the weight, then the retardation arising from the friction will, from what has been faid, remain the fame, and therefore the whole acceleration of the body will not be altered; confequently the body ought, upon this supposition, still to describe the same space in the same time. Hence, by observing the spaces described in the same time, when both the body and the moving force are increased in the same ratio, we may determine whether the friction increases in proportion to the weight. The following experiments were therefore made in order to ascertain

Exp. 1. A body weighing 10 oz. by a moving force of 4 oz. described in 2" a space of 51 inches; by loading the body with 10 oz. and the moving force with 4 oz. it described 56 inches in 2"; and by loading the body again with 10 oz. and the moving force with 4 oz. it desoribed 63 inches in 2".

Exp. 2. A body, whose weight was 16 oz. by a moving force of 5 oz. described a space of 49 inches in 3"; and by loading the body with 64 oz. and the moving force with 20 oz. the space described in the same time was 64 inches.

Exp. 3. A body weighing 6 oz by a moving force of $2\frac{\pi}{r}$ oz. described 28 inches in 2"; and by loading the body with 24 oz. and the moving force with 10 oz. the space described in the same time was 54 inches.

Exp. 4. A body weighing 8 oz. by a moving force of 4 oz. described 33 inches in 2"; and by loading the body with 8 oz. and the moving force with 4 oz. the space described in the same time was 47 inches.

Exp. 5. A body whose weight was 9 oz. by a moving force of $4\frac{1}{2}$ oz. described 48 inches in 2'; and by loading the body with 9 oz. and the moving force with 41 oz. the space described in the same time was 60 inches.

Exp. 6. A body weighing 10 oz. by a moving force of

I lion. 3 oz. described 20 inches in 2"; by loading the body with 10 oz. and the moving force with 3 oz. the space described in the same time was 31 inches; and by loading the body again with 30 oz. and the moving force with 9 oz. the space described was 34 inches in 2".

From these experiments, and many others which it is not necessary here to relate, it appears, that the space described is always increased by increasing the weight of the body and the accelerative force in the same ratio; and as the acceleration arising from the moving force continued the same, it is manifest, that the retardation arising from the friction must have been diminished, for the whole accelerative force must have been increased on account of the increase of the space described in the same time; and hence (as the retardation from

Quantity of friction friction varies as Quantity of matter the quantity of friction increases in a less ratio than the quantity of mat-

ter or weight of the body.

6. We come now to the last thing which it was proposed to determine, that is, whether the friction varies by varying the furface on which the body moves. Let us call two of the furfaces A and a, the former being the greater, and the latter the less. Now the weight en every given part of a is as much greater than the weight on an equal part of A, as A is greater than a; if therefore the faiction was in proportion to the weight, cateris paribus, it is manifest, that the friction on a would be equal to the friction on A, the whole friction being, upon fuch a supposition, as the weight on any given part of each surface multiplied into the number of fuch parts or into the whole area, which products, from the proportion above, are equal. But from the last experiments it has been proved, that the friction on any given surface increases in a less ratio than the weight; consequently the friction on any given part of a has a less ratio to the friction on an equal part of A than A has to a, and hence the friction on a is less than the friction on A, that is, the smallest surface has always the least friction.

As this conclusion is contrary to the generally received opinion, Mr Vince thought it proper to confirm it by a let of experiments made with different bodies of exactly the same degree of roughness on their two fur-

faces.

Exp. 1. A body was taken whose flat surface was to its edge as 22:9, and with the fame moving force the body described on its stat side 33 r inches in 2", and on its edge 47 inches in the fame time.

Exp. 2. A fecond body was taken whose flat furface was to its edge as 32:3, and with the same moving. force it described on its flat fide 32 inches in 2", and on its edge it described 371 inches in the same time.

Exp. 3. He took another body and covered one of its furfaces, whose length was 9 inches, with a fine rough paper, and by applying a moving force, it deferibed 25 inches in 2"; he then took off some paper from the middle, leaving only 3 of an inch at the two ends, and with the same moving force it described 40 inches in the same time.

its furfaces, whose length was 9 inches, covered with a motion without any acceleration; in which ease the fine rough paper, and by applying a moving force it friction must be just equal to the accelerative force. deteribed 42 inches in 2"; fome of the paper was then The body was then stopped, when it appeared, that the taken off from the middle, leaving only to inches at fame moving force which had kept the body in motion be-

the two ends, and with the same moving force it de- Priction. scribed 54 inches in 2"; he then took off more paper, leaving only i of an inch at the two ends, and the body then described, by the same moving force, 60 inches in the same time.

In the two last experiments the paper which was taken off the furface was laid on the body, that its weight

might not be altered.

Exp. 5. A body was taken whose flat surface was to its edge as 30: 17; the flat fide was laid upon the horizontal plane, a moving force was applied, and the stage was fixed in order to stop the moving force, in consequence of which the body would then go on with the velocity acquired until the friction had destroyed all its motion; when it appeared from a mean of 12 trials that the body moved, after its acceleration ceased. 57 inches before it stopped. The edge was then applied, and the moving force descended through the same space; and it was found, from a mean of the same number of trials, that the space described was 7 inches before the body lost all its motion, after it ceased to be accelerated.

Exp. 6. Another body was then taken whose flat furface was to its edge as 60: 19, and, by proceeding as before, on the flat surface it described, at a mean of 12 trials, $5\frac{1}{8}$ inches, and on the edge $6\frac{11}{24}$ inches, before

it stopped, after the acceleration ceased.

Exp. 7. Another body was taken whose flat surface was to its edge as 26: 3, and the spaces described on these two furfaces, after the acceleration ended, were, at a mean of ten trials, 43 and 750 inches respectively.

From all these different experiments it appears, that the smallest surface had always the least friction, which agrees with the confequence deduced from the confideration that the friction does not increase in fo great a ratio as the weight; we may therefore conclude, that the friction of a body does not continue the same when it has different surfaces applied to the plane on which it moves, but that the smallest surface will have the least?

To the experiments inflituted by Mr Ferguson and 3 others, from which conclusions have been drawn to different from these, our author makes the following objections: It was their object to find what moving force would just put a body at rest in motion; and having, as they thought, found it, they thence concluded, that the accelerative force was then equal to the friction. But it is manifest, as Mr Vince observes, that any forcewhich will put a body in motion must be greater thanthe force which opposes its motion, otherwise it coulds not overcome it; and hence, if there were no other objection than this, it is evident, that the friction coulds not be very accurately obtained: but there is another objection which totally destroys the experiment so faras it tends to shew the quantity of friction, which is the strong cohesion of the body to the plane when it hes at reft; and this is confirmed by the following experiments. 1/2, A body of 12/2 oz. was laid upon an horizontal plane, and then loaded with a weight of 8lb. and fuch a moving force was applied as would, Exp. 4. Another body was taken which had one of when the body was just put in motion, continue that

Friction, fore, would not put it in motion, and it was found ne- pose of producing artificial cold. Some of these mix. Frigor cessary to take off 41 oz. from the body before the fame moving force would put it in motion; it appears therefore, that this body, when laid upon the plane, at rest, acquired a very strong cohesion to it. 2dly, A body whose weight was 16 oz. was laid at rest upon the horizontal plane, and it was found that a moving force of 6 oz. would just put it in motion; but that a moving force of 4 oz. would, when it was just put in motion, continue that motion without any acceleration, and therefore the accelerative force mult then have been equal to the friction, and not when the moving force of 6 oz. was applied.

From these experiments therefore it appears, how very confiderable the cohefion was in proportion to the friction when the body was in motion; it being, in the latter case, almost id, and in the former it was found to be very nearly equal to the whole friction. All the conclusions therefore deduced from the experiments, which have been instituted to determine the friction from the force necessary to put a body in motion, have manifestly been totally false; as such experiments only shew the refistance which arises from the cohesion and fric-

tion conjointly.

Our author concludes this part of his fubject with the following remark upon no 5: "It appears from all the experiments (fays he) which I have made, that the proportion of the increase of the friction to the increase of the weight was different in all the different bodies which were made use of; no general rule therefore can be established to determine this for all bodies, and the experiments which I have hitherto made have not been fufficient to determine it for the same body."

He then proceeds to establish a theory upon the principles which he has deduced from his experiments. That theory is comprehended in five propolitions, of which the object of the first is " to find the time of defcent, and the number of revolutions made by a cylinder rolling down an inclined plane in confequence of

its friction.

1 200

11. "To determine the space through which a body, projected on an horizontal plane with a given velocity, will move before it stops, or before its motion becomes uniform.

III. "To find the centre of friction.

IV. "To determine, from the given velocity with which a body begins to revolve about the centre of its bafe, the number of revolutions which that body will make before all its motion be destroyed.

point of a body affected by friction when it descends

down any inclined plane."

To give the folutions of these problems, with the corollaries deduced from them, would swell this article to very little purpofe; for they would be unintelligible to the mere mechanic; and the mathematician will either perspicuous.

sorter to a , a make take

tures are enumerated under the title Cold (Encycl.), and a much more accurate lift of them is given, together with the principle upon which they produce their effect, in the article CHEMISTRY, nº 282. (Suppl.) There is one mixture, however, not mentioned in that lift, which was employed by Seguin, and feems, on many accounts, to be the most eligible that has yet been proposed. Considering the muriats (fee CHE-MISTRY-Index, Suppl.) as a class of falts best fuited for the purpofe, he gave the decided preference to muriat of lime in chrystals; and his method was to mix the crystals, previously pulverised, with an equal weight of uncompressed fnow.

By means of this mixture Mr W. H. Pepys junior, of the London Philosophical Society, with the affistance of fome friends, froze, on the 8th of February 1799, 56 lbs. averdupoife of mercury into a folid mass. The mercury was put into a strong bladder and well fecured at the mouth, the temperature of the laboratory at the time being + 33°. A mixture confisting of muriat of lime 2 lb. at + 33°, and the fame weight of frow at + 32° gave - 42° (A). The mercury was put as gently as possible into this mixture (to prevent a rupture of the bladder), by means of a cloth held at the four corners. When the cold mixture had robbed the mercury of fo much of its heat as to have its own temperature thereby raifed from - 42° to +5, another mixture, the same in every respect as the last, was made, which gave, on trial with the thermometer,

— 43°. The mercury was now received into the cloth, and put gently into this new mixture, where it was left to be cooled still lower than before.

In the mean time five pounds of muriat of lime, in a large pail made of tinned iron, and japanned infide and outfide, was placed in a cooling mixture in an earthenware pan. The mixture in the pan, which confifted of 4 lb. of muriat of lime and a like quantity of fnow, of the fame temperature as the former, in one hour reduced the 5 lb. of muriat in the pail to - 15°. The mixture was then emptied ont of the earthen pan, and four large corks, at proper distances, placed on its bottom, to ferve as rests for the japanned pail which was now put into the pan. The corks answered the purpose of infulating the inner veffel, while the exterior one kept off the furrounding atmosphere, and preserved the air

between the two at a low temperature.

To the 5 lb. of muriat of lime which had been cooled, as already noticed, to - 15°, and which still re-V. "To find the nature of the curve described by any mained in the metallic vessel, was now added fnow, uncompressed and free from moisture, at the usual temperature of + 32°. In less than three minutes the mixture gave a temperature of - 62°: a degree of cold which perhaps was never before produced in this country, being 94° below the freezing point of water.

The mercury, which, by immersion in the second folve them for himfelf, or have recourse to the original cooling mixture to which it was exposed, was, by this memoir, where he will find folutions at once elegant and time reduced to - 30°, was now, by the means employed before, cautiously put into the last made mixture FRIGORIFIC MIXTURES, are those which expe- of the temperature of - 62°. A hoop, with net-work rience has taught philosophers to employ for the pur- fastened to its upper edge, and of such a breadth in the

na formation and provided the second rimit

rut to be creler (A) The thermometer made use of in this experiment was filled with tinged alcahol, and accurately divided according to Fahrenheit's scale. of the rim that the net-work, when loaded with the bladder of mercury, could not reach its lower edge, was at the bottom of the mixture, to prevent the bladder from coming in contact with the veffel; by which means the mercury was suspended in the middle of the mixture. As foon as the bladder was fafely deposited on the network, the veffels were carefully covered over with a cloth, to impede the passage of heat from the surround ing atmosphere into the freezing materials. The condensation of moisture from the atmosphere by the agency of so low a temperature was greater than could have been expected: it floated like fleam over the veffels, and, but for the interposed covering, would have given the mixture more temperature than was desirable.

After one hour and forty minutes they found, by means of a fearcher introduced for the purpose, that the mercury was folid and fixed. The temperature of the mixture at this time was - 46, that is, 16° higher

than when the mercury was put into it.

Our young philosophers having neglected to sling the hoop and net-work in fuch a manner as might have enabled them to lift it out of the mixture at once, with the bladder and its contents, were obliged to turn out the whole contents of the pail into a large evaporating capfule made of iron. This was not effected without the mercury striking against its bottom and being fractured, though it received a considerable increase of temperature from the capfule. The fracture was fimilar to that of zinc, but with parts more cubical. The larger pieces were kept for fome minutes before fusion took place, while others were twifted and bent into various forms, to the no fmall gratification and furprife of those who had never witnessed or expected to fee such an effect produced on fo fufible a metal.

In experiments of the kind here described, all the exterior veffels should be of earthen-ware or wood, which being bad conductors of heat, prevent the ingredients from receiving heat from the atmosphere and furrounding objects with the fame facility that they would through metals; and, for a fimilar reason, the interior vessels are best of metal, that they may allow the heat to pass more readily from the substance to be cooled into the frigorific mixture employed for that

Muriat of lime is certainly the most powerful, and at the same time the most economical substance that can be employed for producing artificial cold; for its first cost is a mere trisle, being a residuum from many chemical processes, as the distillation of pure ammonia, &c. and often thrown away: besides, it may be repeatedly used for similar experiments, nothing being neceffary for this purpose but filtration and evaporation to bring it to its first state. The evaporation should be carried on till the folution becomes as thick as a strong fyrup, and upon cooling the whole will be crystallised: it must then be powdered, put up in dry bottles, well corked, and covered with bladder or cement to prevent liquefaction; which otherwise would soon take place, owing to the great affinity the muriat has for

The powerful effects produced by the frigorific mixture of muriat of lime and fnow, present a wide field for experiments to determine the possibility of fixing some of the gases by intense cold. And we are happy to be informed by Mr Pepys, that, as foon as an SUPPL. Vol. I. Part II.

opportunity offers, he and his friends mean to make some experiments with that view, and to communicate the result of them to the editor of the valuable miscellany * from which we have taken this account of his * The Phiexperiment on mercury.

FRIO, a small island on the coast of the Brazils, ft. Magazine. tuated in 32° 2' fouth lat. and 41° 31' 45" west lon. The land of Frio is high, with a hollow in the middle, which gives it, at a distance, the resemblance of two separate islands. The passage between the island and the continent is about a mile broad, and feemed to Sir Erasmus Gower to be clear from shoals.

FROST, as is well known in Scotland, is particularly destructive to the blossom of fruit trees; and the following method of fecuring fuch trees from being damaged by early frosts may be acceptable to many of our readers. A rope is to be interwoven among the branches of the tree, and one end of it brought down fo as to be immerfed in a bucket of water. The rope, it is faid, will act as a conductor, and convey the effects of the frost from the tree to the water. This idea is not new; for the following passage may be found in Colerus: "If you dig a trench around the root of a tree, and fill it with water, or keep the roots moift till it has bloomed, it will not be injured by the frost. Or, in spring, suspend a vessel filled with water from the tree. If you wish to preserve the bloom from being hurt by the frost, place a vessel of water below it, and the frost will fall into it." Philosophical Magazine, no 11.

FUEL, whatever is proper to burn, or make a fire, either for warming a room or dreffing victuals. The fuel most generally used in Great Britain is pit coal, which is a very expensive article; and that expence is greatly increased by the waste of coal occasioned by the injudicious manner in which fires in open chimneys are commonly managed. The enormous waste of fuel in London, for instance, may be estimated by the vast dark cloud which continually hangs over that great metropolis, and frequently overshadows the whole country far and wide; for this dense cloud is certainly composed almost entirely of unconfumed coal, which has escaped by the chimneys, and continues to fail about in the air, till, having lot the heat which gave it volatility, it falls in a dry shower of extremely fine black dust to the ground, obscuring the atmosphere in its descent, and frequently changing the brightest day into more than Egyptian darkness.

"I never (says Count Rumford) view from a distance, as I come into town, this black cloud which hangs over London, without wishing to be able to compute the immense number of chaldrons of coals of which it is composed; for could this be ascertained, I am perfuaded to firiking a fact would awaken the curiofity, and excite the aftonishment of all ranks of the inhabitants; and perhaps turn their minds to an object of economy to which they have hitherto paid little attention."

The object to which the benevolent author more particularly wishes to direct the public attention, is the lighting of a coal fire, in which more wood should be employed than is commonly used, and fewer coals; and as foon as the fire burns bright, and the coals are well lighted, and not before, more coals should be added to increase the fire to its proper fize.

Kindling balls, composed of equal parts of coal,charcoal, and clay, the two former reduced to a fine powder. Fuel.

clay moistened with water, and then formed into balls of the fize of hens eggs, and thoroughly dried, might be used with great advantage instead of wood for kindling fires. These kindling balls may be made so inflammable as to take fire in an inftant and with the fmallest spark, by dipping them in a strong folution of nitre and then drying them again; and they would neither be expensive nor liable to be spoiled by long keeping. Perhaps a quantity of pure charcoal, reduced to a very fine powder, and mixed with the folution of nitre in which they are dipped, would render them still more

The Count thinks that the fires which are made in the open chimneys of elegant apartments might be greatly improved by preparing the fuel; for nothing (fays he) was ever more dirty, inelegant, and difgusting

than a common coal fire.

Fire balls, of the fize of goole eggs, composed of coal and charcoal in powder, mixed up with a due proportion of wet clay, and well dried, would make a much more cleanly, and in all respects a pleasanter fire than can be made with crude coals; and, he believes, would not be more expensive fuel. In Flanders, and in several parts of Germany, and particularly in the duchies of Juliers and Bergen, where coals are used as fuel, the coals are always prepared before they are used, by pounding them to a powder, and mixing them up with an equal weight of clay, and a sufficient quantity of water to form the whole into a mass, which is kneaded together and formed into cakes; which cakes are afterwards well dried and kept in a dry place for use. And it has been found, by long experience, that the expence attending this preparation is amply repaid by the improvement of the fuel. The coals, thus mixed with clay, not only burn longer, but give much more heat than when they are burnt in their crude state.

It will doubtless appear extraordinary to those who have not confidered the fubject with some attention, that the quantity of heat produced in the combustion of any given quantity of coals should be increased by mixing the coals with clay, which is certainly an incombustible body; but the phenomenon may be explained

in a satisfactory manner.

The heat generated in the combustion of any small particle of coal existing under two distinct forms, namely, in that which is combined with the flame and smoke which rife from the fire, and which, if means are not found to stop it, goes off immediately by the chimney and is loft, - and the radiant heat which is fent off from the fire in all directions in right lines: - It is therefore reasonable to conclude, that the particles of clay, which are furrounded on all fides by the flame, arrest a part at least of the combined heat, and prevent its escape; and this combined heat, so arrested, heating the clay red hot, is retained in it, and being changed by this operation to radiant heat, is afterwards emitted, and may be directed and employed to ufeful purposes. In the composition of fire balls, the Count thinks it probable that a certain proportion of chaff, of straw cut very fine, or even of faw-duft, might be employed with great advantage.

FULLING OF WOOLLEN CLOTHS (fee the method of performing the operation under the article FULLING, Encycl.) depends, like FELTING, fo entirely upon the tructure of wool and hair, that the following observa-

powder, well mixed and kneaded together, with the tions, which are not unimportant, will be intelligible to Fuln every reader who has perused that article in this Sup-

The asperities with which the surface of wool is every where furrounded, and the disposition which it has to assume a progressive motion towards the root, render the spinning of wool, and making it into cloth, difficult operations. In order to spin wool, and afterwards to weave it, we are obliged to cover its fibres with a coating of oil, which, filling the cavities, renders the asperities less sensible; in the same way as oil, when rubbed over the furface of a very fine file, renders it still less rough. When the piece of cloth is finished, it must be cleanfed from this oil; which, besides giving it a disagreeable smell, would cause it to soil whatever it came in contact with, and would prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil, it is carried to the fulling-mill,. where it is beat with hammers in a trough full of water, in which some clay has been mixed; the clay combines with the oil, which it separates from the cloth, and both together are washed away by the fresh water which is brought to it by the machine; thus, after a certain time, the oil is entirely washed out of the cloth.

But the scouring of the cloth is not the only object in fulling it; the alternate pressure given by the mallets to the piece of cloth, occasions, especially when the scouring is pretty far advanced, an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compose one of the threads, whether of the warp or the woof, assume a progreffive movement, introduce themselves among those of the threads nearest to them, then into those which follow; and thus, by degrees, all the threads, both of the warp and the woof, become felted together. The cloth, after having, by the above means, become shortened in all its dimensions, partakes both of the nature of cloth and of that of felt; it may be cut without being subject to ravel, and, on that account, we are not obliged to hem the edges of the pieces of which clothes are made. Lastly, As the threads of the warp and those of the woof are no longer fo distinct and separated from each other, the cloth, which has acquired a greater degree of thickness, forms a warmer clothing. Knit worsted also is, by fulling, rendered less apt to run, in case a stitch should drop in it.

FULMINATING GOLD. See CHEMISTRY, Suppl.

nos 849 and 850. FULMINATING Silver.

Mr Berthollet, the inventor of fulminating filver, having contented himself with a general and concise description of this subject, many practical chemists have failed in their attempts to prepare it; and others, forming their opinions from the specimens which they had made, have been exposed to great danger; as will appear from the following relation:

An ounce of fine filver was diffolved in the course of eight hours in an ounce of pure nitrous acid, of the London Pharmacopæia, diluted previously with three ounces of distilled water in a glass matrass. The solution being poured off, the refiduary black powder and the matrass were washed with seven or eight ounces of warm distilled water, and this was added to the folution. The black powder, being gold, was rejected; some gold being thus separable from any filver of commerce.

To the foregoing diluted folution, pure lime-water

prepared

Fi ina- prepared with distilled water was added gradually; for the folution ought not to be poured into the lime-water. When about thirty pints of lime-water had been expended, and the precipitate had subsided, more limewater was added, by fucceffive pints, as long as it caufed any precipitation. For it was deemed fitter that the precipitation should not be perfected, than that an exeefs of lime water should be used; the earthy pelliele of the exceffive lime water being apt to mix with the precipitate. The clear liquor being poured away, the precipitate was poured off, and washed into a filter.

When the faline liquor had drained from it, two ounces of distilled water were poured on the magma; and when this water had passed, fresh portions were sueceffively added and paffed, until the whole quantity of water thus expended in washing away the nitrous cal-

careous falt amounted to a quart.

The filter being then unfolded, to let the magma of oxyd of filver spread on the flattened paper, it was placed on a chalk-stone to accelerate the exsiceation, and was gradually dried in the open air; a cap of paper be-

ing placed loofely over it to exclude the dust. When the weather ferved, the cap was removed, to

expose the oxyd to the rays of the fun; although this was not deemed necessary; and exsiccation was promoted by cutting the oxyd into thin slices. When perfeetly dry it weighed 1 oz. 4 dwts. and about one-fifth of it was confidered as oxygen.

When aqua ammoniæ puræ of any pharmacopæia is used with this oxyd, either in the small quantity which blackens it completely, or in a greater quantity, the black matter which fubfides, and which has been reprefented by fystematic writers as the fulminating compound, has no fuel property, any farther than may be owing to the matter deposited from the alkaline solution

during the exficeation. The alkaline liquor containing the fulminating filver ought to be poured off from the infoluble powder, and exposed in a shallow vessel to the air. In consequence of the exhalation, black shining crystals form on the furface only, and foon join to form a pellicle. As this pellicle adheres a little to the fides of the veffel, or maintains its figure, the liquor may be poured off by a gentle inclination of the veffel.

This liquor will yield another pellicle in the same way; but the third or fourth pelliele will be paler than the former, and weaker in the explosion. The first pellicles, when flowly dried, explode by the touch of a feather, or by their being heated to about 96°.

The quantity of water in the ordinary aqua ammoniæ puræ renders it less active in the folution of the oxyd, and is an impediment to the speedy formation and separation of the fulminating silver; and an experimenter who has often used twenty grains of the oxyd to produce successive pellicles of fulminating silver, which may be separately exploded with safety, and who has perceived that the pellicles never explode whilft wet, if they be not heated, would, in all probability, refolve on the following improvement, and expose himself to the unforeseen danger of it.

Distilled water was impregnated with as much pure ammoniae as it could eafily retain under the ordinary temperature of the air. A quantity of this strong ammoniaeal liquor, equal in bulk to a quarter of an ounce of water, was placed in a small bottle, and 24 grains of

the oxyd of filver, ground to fine powder, were added. Function The bottle, being almost filled, was corked, to prevent the formation of that film which usually appeared in confequence of the exhalation of the ammoniae in other

experiments.

During the solution of the oxyd, bubbles of the gafeous kind arose from it, and the solution acquired a blue colour. As no film appeared, the bottle was agitated three or four times in the course of as many hours, in order to promote the folution of a small quantity of blackened oxyd which remained at the bottom. The experimenter confidering this as an ample provision for twenty different charges, to be exploded in different circumstances, in the presence of the society, intended to pour off the folution into as many fmall veffels, and to weigh the refiduary black powder, after allowing two hours more for the folution.

On the fixth hour he took his usual precaution of wearing spectacles; and observing that a small quantity of black powder still remained undissolved, and that no film was yet formed at the furface, he took the bottle by the neck to shake it; knowing that it might explode by the heat of his hand, if he were to grafp it, and that the explosion in this circumstance might wound him

dangeroufly.

In the instant of shaking, it exploded with a report that stunned him. The bottle was blown into fragments fo fmall as to appear like glass coarsely powder-The hand which held it was impressed as by the blow of a great hammer, and loft the fense of feeling for some seconds; and about 52 small grains of glass were lodged, many of them deeply, in the skin of the palm and fingers. The liquor stained his whole drefs, and every part of the skin that it touched. Thus it appeared that fulminating filver may be made which will explode even when cold and wet, by the mere diflurbance of the arrangement of its parts, in the aqueous

In fublequent experiments, privately and earefully conducted, it feemed that the property of exploding in the cold liquor, by mere commotion, depended on the unufual quantity or proximity of the explosive molecules in a given bulk of the liquor. And the flat bottoms, as well as the fides, of the thick veffels of glass or potters-ware, whether they flood on boards or iron plates, were always beaten to fmall fragments.

This afforded a curious instance of the possible equilibrium between the powers tending to retain the caloric and those which effect the expulsion of it; and experiments and confiderations of this kind feemed to promise a true solution of the phenomena of Rupert's

FUNCTION, a term used in analytics for an algebraical expression any how compounded of a certain letter or quantity with other quantities or numbers; and the expression is said to be a function of that letter or quantity. Thus a = 4x, or $ax + 3x^2$,

or $2x - a\sqrt{a^2 - x^2}$, or x^c , or c^x , is each of them a function of the quantity x.

FURD-Y-HUCKEECUT, in Bengal, fignifies a paper of description.

FURD-y Sorval, paper of request.

FUST, in architecture, the shaft of a column, or the part comprehended between the base and the capital, called also the naked.

Gaguedi. CAGUEDI, a tree peculiar to Lamalmon, in Abysfinia, is thus described by Mr Bruce. The leaves are long, and broader as they approach the end. The point is obtufe; they are of a dead green, not unlike the willow, and placed alternately one above the other on the stalk. The calix is composed of many broad scales lying one above the other, which operates by the preffure upon one another, and keeps the calix that before the flower arrives at perfection. The flower is mono-petolous, or made of one leaf; it is divided at the top into four fegments; where thefe end, it is covered with a tuft of down, refembling hair, and this is the cafe at the top also. When the flower is young and unripe, they are laid regularly fo as to inclose one another in a circle. As they grow old and expand, they feem to lose their regular form, and become more confused, till

at last, when arrived at its full perfection, they range Gagu themselves parallel to the lips of the calix, and perpendicular to the stamina, in the same order as a lose. The common receptacle of the flower is oblong, and very capacious, of a yellow colour, and covered with fmall leaves like hair. The stile is plain, simple, and upright, and covered at the bottom with a tuft of down, and is below the common receptacle of the

Our author fays that he has observed, in the middle of a very hot day, that the flowers unbend themselves more, the calix feems to expand, and the whole flower to turn itself towards the fun in the same manner as does the fun-flower. When the branch is cut, the flower dries as it were instantaneously, fo that it seems to contain very little humidity.

GALVANISM.

Galvanism

ALVANISM, is the name now commonly given to the influence discovered nearly eight years ago improperly by the celebrated Galvani, professor of anatomy at Bomal electri- logna, and which, by him and fome other authors, has been called animal electricity. We prefer the former name, because we think it by no means proved, that the phenomena discovered by Galvani depend either upon the electric fluid, or upon any law of animal life. While that is the case, it is surely better to distinguish a new branch of science by the name of the inventor, than to give it an appellation which probably may, and, in our opinion, certainly does, lead to an erroneous theory.

M. Galvani was engaged in a fet of experiments, the object of which was to demonstrate, if possible, the dependence of muscular motion upon electricity. In the course of this investigation, he had met with several new and striking appearances which were certainly electrical; foon after which, a fortunate accident led to the difcovery of the phenomena which constitute the chief subject of this article. The strong resemblance which these bore to the electrical facts which he had before observed, led almost irrefishibly to the conclusion that they all depended upon the same cause. This opinion he immediately adopted; and his subsequent experiments and reasonings were naturally directed to support it. The splendor of his discovery dazzled the imaginations of those who prosecuted the enquiry; and for some time his theory, in fo far at least as it attributed the whole to the agency of the electric fluid, was fanctioned by universal approbation. Of late, however, this opinion has rather loft ground; and there are now many philofophers who confider the phenomena as totally unconnected with electricity.

Object of

Difcovery

of galva.

nifm.

We propose, in the first place, to enumerate the chief this article facts which have been ascertained on the subject; we shall then enquire, whether or not the cause of the appearances be the electric fluid; and, thirdly, we shall examine how far it has been proved, that this cause is necessarily connected with animal life.

Whilst Galvani was one day employed in diffecting a frog, in a room where some of his friends were amufing themselves with electrical experiments, one of them having happened to draw a spark from the conductor

at the fame time that the professor touched one of the nerves of the animal, its whole body was inflantly shaken by a violent convulfion. Aftonished at the phenomenon, and at first imagining that it might be owing to his having wounded the nerve, he pricked it with the point of his knife, to affure himself whether or not this was the case, but no motion of the frog's body was produced. He now touched the nerve with the inftrument as at first, and directed a spark to be taken at the fame time from the machine, on which the contractions were renewed. Upon a third trial, the animal remained motionless; but observing that he held his knife by the handle, which was made of ivory, he changed it for a metallic one, and immediately the movements took place, which never was the case when he used an electric substance.

After having made a great many fimilar experiments with the electrical machine, he refolved to profecute the subject with atmospheric electricity. With this view he raised a conductor on the roof of his house, from which he brought an iron wire into his room. To this he attached metal conductors, connected with the nerves of the animals deftined to be the fubjects of his experiments; and to their legs he fastened wires which reached the floor. These experiments were not confined to frogs alone. Different animals, both of cold and warm blood, were subjected to them; and in all of them confiderable movements were excited whenever it lightned. These preceded thunder, and corresponded with its intensity and repetition; and even when no lightning appeared, the movements took place when any ftormy cloud passed over the apparatus. That all these appearances were produced by the electric fluid, was obvious.

Having foon after this suspended some frogs from the iron palisades which surrounded his garden, by means of metallic hooks fixed in the spines of their backs, he observed that their muscles contracted frequently and involuntarily as if from a shock of electricity. Not doubting that the contractions depended on the electric fluid, he at first fuspected that they were connected with changes in the state of the atmosphere. He soon found, however, that this was not the cafe; and having varied, in many different ways, the circumstances in

which the frogs were placed, he at length discovered that he could produce the movements at pleasure by touching the animals with two different metals, which, at the fame time, touched one another either immediately or by the intervention of some other substance capable of conducting electricity.

All the experiments that have yet been made may be reduced to the following, which will give the otherwife uninformed reader a precise notion of the subject.

Lay bare about an inch of a great nerve, leading to any limb or muscle. Let that end of the bared part which is farthest from the limb be in close contact with a bit of zinc. Touch the zinc with a bit of filver, while another part of the filver touches, either the naked nerve, if not dry, or, whether it be dry or not, the limb or muscle to which it leads. Vielent contractions are produced in the limb or muscle, but not in any muscle on the other side of the zinc.

Or, touch the bared nerve with a piece of zinc, and touch, with a piece of filver, either the bared nerve, or the limb; no convultion is observed, till the zinc and

filver are also made to touch each other.

A fact fo new, illustrated by many experiments and much ingenious reasoning, which Professor Galvani foon published, could not fail to attract the attention of physiologists all over Europe; and the result of a vast number of experiments, equally cruel and furprifing, has been from time to time laid before the public by Valli, Fowler, Monro, Volta, Humbolt, and others

Frogs, unhappily for themselves, have been found the most convenient subjects for these experiments, as they retain their muscular irritability and susceptibility of the galvanic influence very long. Many hours after they have been decapitated, or have had their brain and spinal marrow destroyed, strong convulsions can be produced in them by the application of the metals. leg separated from the body will often continue capable of excitement for feveral days. Nay, very diffinct movements have been produced in frogs pretty far advanced in the process of putrefaction. Different kinds of fishes, and many other animals both of cold and warm blood, have been subjected to similar experiments, and have exhibited the same phenomena; but the warm blooded animals lofe their fufceptibility of galvanism, as of every other stimulus, very foon after death.

Almost any two metals will produce the movements; but, it is believed, the most powerful are the following, in the order in which they are here placed: 1. Zinc; 2. Tin; 3. Lead; in conjunction with, 1. Gold; 2. Silver; 3. Molybdena; 4. Steel; 5. Copper. Upon this point, however, authors are not perfectly agreed.

The process by which these fingular phenomena are produced, confifts in effecting, by the use of the exciting apparatus, a mutual communication between any two points of contact, more or less distant from one another, in a fyltem of nervous and muscular organs. The fphere of this mutual communication may be re-

garded as a complete circle, divided into two parts. That part of it which confits of the organs of the excitatory animal under the experiment, has been called the ani-arcs. mal arc; that which is formed by the galvanic inftruments has been called the excitatory arc. The latter usually consists of more pieces than one; of which some are named flays, braces, &c. others communicators, from their respective uses.

A very numerous train of experiments on galvanism Experihas been made by a committee of the Physical and Ma-ments of the matical Class of the National Institute of France; Institute. and as their report comprehends a valt number of the most important facts which are yet known on the subject, we shall present our readers with the substance of

The immense mass of matter which resulted from the experiments of the committee, is, in their report, prefented, not in the order in which the experiments were made, but in a fort of classification, by means of which a more diffined knowledge of the subject is obtained at one view. The facts are arranged under these fix heads. 1st, Refults of the different combinations and dispositions of the parts of the animal arc. 2d, Account of what has been observed of the nature and the different dispositions of the excitatory arc. 3d, Circumstances not entering into the composition of the galvanic circle, which, nevertheless, by their influence, modify, alter, or entirely prevent the success of the experiments. 4th, Means proposed for varying, diminishing, or restoring. the fenfibility to galvanism. 5th, Attempts to compare the phenomena of galvanism with those of electricity. 6th, Additional experiments, performed by M. Humboldt, in the presence of the members of the committee; which have a reference to several of the proofs stated in the foregoing articles.

I. To the number of twenty experiments were made On the anison the animal arc. The first seven of these were di-mal arc. rected to afcertain the relations between the nerves and those muscles over which they are distributed. In the last thirteen, the nerves were cut asunder, or subjected to ligatures; the fection or ligature being always between the extremities of the arc. Nerves taken from different animals, or from different parts of the same animal, and joined in one and the same arc, were among the particular subjects of these experiments; as were also the solitary nerve, and the solitary muscle, included between the extremities of the excitatory arc. There were interposed, too, in the course of these experiments, portions of nerves, and of muscles, distinct from those parts. And, in some of the experiments, the animal was without the skin and the epidermis.

The following are inferences which have been deduced

from these experiments:

1. The animal arc may confift either of nerves and Inferences muscles together, or of nerves alone, without muscles.

2. Nerves are, therefore, the effential part of the a-

(A) The members of the committee were, M. M. Coulomb, Sabbatier, Pelletan, Charles, Fourcroy, Vauquelin, Guyton, alias Morveau, and Hallé. M. M. Venturi, De Modene, and M. Humboldt, affifted in the experiment. (B) We are strongly inclined to doubt the truth of this proposition. Dr Fowler was at first led to think that contractions could be excited in a limb without the metals having any communication with it, except through the medium of the nerve. Recollecting, however, that a very small quantity of moisture serves as a conductor of galvanism, he suspected, and our opinion perfectly coincides with his, that in every case where contractions.

nimal arc; for the muscles are always more or less intersected by the nerves; and are, consequently, in part, a nervous organ.

3. All the parts of the animal arc must be either mutually continuous, or at least contiguous to one another. But even contiguity is sufficient to enable the

galvanic phænomena to take place.

4. The fection or ligature of a nerve interrupts not the galvanic phænomena, if the parts which are cut atunder or bound up still remain in close contiguity to one another.

5. No diversity of the parts forming the animal arc, though these be taken from different parts of the same animal, or even from different animals, will have power to impair its galvanic susceptibility, provided only that

these parts be still mutually contiguous.

6. If the integrity or galvanic susceptibility of the animal arc be suspended by the separation of any of its parts to some distance from one another, it may be restored by the interposition of some substances, not of an animal nature, between the divided parts. Metallic substances are in particular fit for this use. But the mutual contiguity of all the substances entering into the composition of the arc must ever be carefully preferved. Mr Humboldt discovered that a bit of fresh morelle (Helvella mitra Linn.) will supply the place of a part of the nerve.

7. The mufcular organs which indicate, by contrac-

tion, the presence of the galvanic influence, are always those in which the nerves of a complete animal arc have their ulcimate termination.

From this it follows, that the muscles affected by galvanism are always those corresponding to that extremity of the arc which is the most remote from the origin of the nerves of which it is composed.

8. When all the nerves of the animal arc originate towards one of its extremities, then only those muscles which correspond with the opposite extremity are suf-

ceptible of galvanic convultions.

9. When an animal arc confifts of more than one fystem of different nerves, which have all their origin about the middle of the arc, then will the muscles of these several systems of nerves be moved alike at both the extremities of the arc.

10. It feems likewise to appear, from a variety of these experiments, that the opinion of those is inadmissible, who ascribe the phænomena of galvanism to the concurrence of two different and reciprocally corresponding influences, one belonging to the nerve, the other to the muscle, and who compare the relations between the nerve and the muscle, in these phænomena, to those between the interior and the exterior coating of the Leyden phial.

11. It appears, lastly, that the covering of the epidermis, in the entire animal body, acts as an obstacle to the decisive display of the effects of galvanism; and

that,

are produced in a limb, without any apparent communication between the metals and the muscles, except through the medium of a nerve, the communication is in fact completed by the moisture upon the surface of the nerve. In this case, the animal arc may be considered as consisting of three pieces, disposed in the following order; the nerve, the muscle, and the water adhering to the surface of the nerve. The latter, indeed, ought rather to be considered as a part of the excitatory arc. "When a nerve (says Dr Fowler), which for some time has been detached from surrounding parts, is either carefully wiped quite dry with a piece of sine mussin, or (less this should be thought to injure its structure) suffered to remain suspended till its moissure has evaporated, no contractions can be excited in the muscles, to which it is distributed, by touching it alone with any two metals in contact with each other; but if it be again moissened with a few drops of water, contractions instantly take place. And, in this way, by alternately drying and moissening the nerve, contractions may at pleasure be alternately suspended and renewed for a considerable time. It may, indeed, be contended, that the moissure softened, and thus restored elasticity and free expansion to the dried cellular membrane surrounding the sibres, of which the trunk of a nerve is composed; and thus, by removing constraint, gave free play to their organization.

"But from observing, that in every other instance where contractions are produced by the mutual contact of the metals, a conducting substance is interposed between them and the muscles as well as between them and the nerve; I think it would be unphilosophical not to allow, that, in the instance in question, the most ture, adhering to the surface of the nerve, formed that requisite communication between the metals and the muscles." We know of no accurate experiment by which it has ever been shewn, that contractions can be produced in a limb without a communication being established between the metals and nerve, and again between the muscles

and the metals, either directly, or through some medium capable of conducting galvanism.

To remove the only objection which can be made to Dr Fowler's experiment, and of which we have feen that he was himfelf aware, namely, that the nerve while dry is incapable of performing its functions, we repeated it in the following manner: A small, but vigorous and lively, male frog was decapitated, and the sciatic nerve being laid bare from the knee npwards, was cut through where it passes out of the pelvis. Fifteen minutes after the head was cut off, the nerve having been cautiously separated from the surrounding parts, and coated with tinfoil in the usual manner, a filver probe was applied to it and its coating, without any other communication with the muscles, and strong contractions took place in the leg. The nerve was now very carefully dried with a piece of fine linen, and the probe was applied as before to the tinfoil and the nerve; no movement whatever took place. Things remaining precisely in this situation, one end of the probe being still in contact with the nerve and its coating, the other end was applied to the muscles of the thigh, and the leg immediately contracted as strongly as ever. Upon moistening the nerve, the contractions were again produced by applying the probe to the nerve and tinfoil alone. We find from this experiment, which we have several times repeated with the utmost care, and with the same result, that the dry nerve retained its sunctions completely. This appears to us perfectly decisive of the question.

together prevent these effects, yet it cannot but very materially diminish them.

II. The Excitatory Arc is usually formed of three different pieces, made of different metals. Of these, one must be in contact with the nerve; the other must touch the muscle; and the third must form the mean of communication between these two. This arrangement, though not indispensably necessary, is at least the most convenient.

In respect to the excitatory arc, the committee examined, 1st, The application of metallic substances to form it: in refpect to which they endeavoured to afcertain the number and the divertity of the pieces of metal, of which this arc may be composed; the metal-lic mixtures or alloys which are capable of being employed for this use; the particular degree of the friction of one metal upon another, which is favourable to the exhibition of the phænomena; the different states, in respect to galvanism, of metals differently mineralized. 2dly, The effects of the use of carbonic substances in forming the excitatory arc. 3dly, The effects in the same formation, of bodies, which are either nonconductors, or elfe very imperfect conductors of electricity, fuch as jet, afphaltus, fulphur, amber, fealingwax, diamond, &c. 4thly, The confequences of the interpolition of water, and of fubftances moiltened with water, between the different parts of the excitatory In forming their excitatory arcs, too, they made themselves the chord of the arc; they introduced into it animal substances which had lost their vitality; they rubbed the supporters with the dry fingers, so as to mark them with nothing but the traces of the perfpiration from the skin. They made, likewise, some experiments for the purpose of ascertaining the relations between, on the one hand, the extent and magnitude of the furfaces of the parts composing the arc, and on the other, the effects produced by its energy. From

that, though from its extreme tenuity, it may not al- their experiments they have also drawn some inferences concerning the relative efficiencies of the feveral constituent parts of the exciting arc. It is impossible for us liere to relate in detail all this train of experiments. The following corollaries express the substance of those general truths, which their authors were led to infer from them.

1. The excitatory are possesses the greatest power of inferences. galvanisin, when it is composed of at least three distinct pieces; each of a peculiar nature: the metals, water, and humid fubstances, carbonaceous matters, and animal fubstances, stripped of the epidermis, being the only materials out of which these pieces may be for-

2. Nevertheless the excitatory arc appears to be not destitute of exciting energy, even when it consists but of one piece or of feveral pieces, all of one proper substance (c). In general it must be owned, identity of nature in the constituent pieces, and particularly in the supports forming the extremities of the arc, diminishes, in a very fenfible manner, its galvanic energy.

3. The slightest difference of nature induced upon the parts, whether by any feeble alloy, or by friction with extraneous fubstances, is at any time sufficient to communicate to the excitatory are that full power in which the identity of its composition may have made it desective.

4. As the animal arc is susceptible of being in part made up of metallic substances, or such others as are adapted to enter into the composition of the excitatory arc; fo, on the other hand, the excitatory arc admits of being in part formed of those substances which are the proper components of the animal arc.

5. The energies of both the excitatory and the ani mal arcs are alike suspended by the separation of their component parts, or at least by the separation of these parts to a certain distance.

6. Even the smallest degree of moisture is sufficient

(c) We do not think it has ever been proved, that one piece of metal, or feveral pieces of the fame metal, are capable of forming the excitatory arc. It is admitted on all hands, that the flightest alloy communicates galvanic energy to a piece of metal; that is, renders it capable of forming the excitatory arc. It is also known, that metallic oxyds are much less persect conductors of galvanism than their corresponding reguli, to make use of an antiquated expression. It appears to us, that in all cases where one metal appears to act, more especially where friction with the singers, or breathing on a piece of metal formerly inert, give it galvanic powers; in all these cases, we think it probable that a slight degree of oxydation, produced in some part of the furface of the metal, gives it activity by destroying the homogeneity of its nature. We do not find that this circumstance has been in general sufficiently attended to. Dr Wells having discovered that charcoal acts powerfully as an exciter when applied along with a metal, found that by friction it also can be rendered capable of acting fingly. What change is thus produced in it we can only conjecture; but that it is fomething which destroys the identity of its structure, rendering it in some measure a licterogeneous substance, must be admitted.

Candour forces us to acknowledge, that in one of M. Humboldt's experiments, it feems very difficult to point out any want of homogeneity in the exciting arc. He put into a clina cup fome mercury exactly purified; he placed the whole near a warm stove, in order that the entire mass might assume an equal temperature: the furface was clear, without the appearance of oxidation, humidity, or dust. A thigh of a frog, prepared in such a manner that a crural nerve and a bundle of muscular fibres of the same length hung down separately, was fuspended by two filken threads above the mercury. When the nerve alone touched the furface of the metal, no irritation was manifested; but as soon as the muscular bundle and the nerve touched the mercury together, they fell into convultions so brisk, that the skin was extended as in an attack of tetanus. This is by far the most decisive experiment which has been tried on the same side of the question; but as it must be admitted, that in most cases two metals are absolutely necessary, and that a single metal often derives activity from circumstances fo slight, that we could not a priori have expected that they were capable of producing any change; we feel ourselves compelled to conclude, that in M. Humboldt's experiment some similar very slight circumstance had escaped unobserved; perhaps some gilding, or ornaments with metallic colours, in a state of oxydation.

to join the parts of the excitatory arc, and to determine their effects upon the animal arc.

7. The influence of the state of the atmosphere, and of furrounding circumstances, upon the success of the experiments of galvanism, is, consequently, very great. In order, therefore, to perform these experiments with due accuracy, the state of the hygrometer, and of other meteorological instruments, must be vigilantly inspected during their progress; and the influence of the persons making the experiment upon the sphere within which it is made, must likewise be carefully attended

8. The experiments which were made to ascertain the nature of the animal arc, together with those made upon the excitatory arc, with a view to the comparison of the effects of the flesh of animals, with or without the epidermis, and of the different effects of this epidermis, when it is wet and when it is dry, appear to fuggest to us, that the epidermis is one of those substances which diminish or interrupt the efficacy of the excitatory arc. The epidermis is, as well as the hairs and briftles of animal bodies, among the number of those substances which deserve the appellation of idioelectrics.

9. Examine the substances which are fit for the formation of the excitatory arc, and you will find that the greater part of those which have been successfully put to this use are substances capable of acting as conductors of the electrical fluid; but that the fubstances which interrupt the operation of galvanism are generally such as are well known also to resist the transmission of electricity.

10. Lastly, it appears, that the galvanic energy depends, not only upon the nature and arrangement of the component parts of the excitatory arc, but on their extent too, and on the magnitudes of their transmitting

furfaces.

III. The committee appear to have used no less theuts rela- care and discernment in experiments upon those circumstances cumstances which, though different from the structure of the galvanic circle and its two constituent arcs, have, however, a decifive influence upon the exhibition of the phanomena of galvanism. Some curious observations were made on the differences in the state of the parts exposed to the galvanic action. It was afcertained, that frogs fresh from the ditches did by no means exhibit the same phænomena as those which had been during some days preserved in the house; nor did the limbs of animals, when recently stripped of the skin, present the same appearances as after they had been subjected to a variety of galvanic experiments; nor were the same effects to be produced upon the parts of animal bodies which, after a certain number of trials, had been left for a while at rest, and then taken up again, as upon those which had been subjected to one continued train of experiments. The committee next examined the variations in the fuccess of the experiments upon a strong lively frog, which may be produced by varying the mode in which the communicator is carried from the one supporter to the other: when the communicator is brought into contact with the fupporter, or is withdrawn from actual contact with it; when the communicator is brought flowly, or when it is brought rapidly, into contact with the supporter; the effects are nearly the same: and a smart convulsion is, in all these cases, produced at the moment of the commencement of the mutual contact, or of its ceffation. But when the frog is fatigued, the effects are diffe-These successive experiments likewise affect the refults of one another, by means even of their succesfion folely. And they are also naturally subject to be influenced by the nature of the media amidst which they are performed; fuch as common air, water, an electrical atmosphere. The following are the inferences which have been deduced from this class of these experiments.

1. In many cases the galvanic energy is excited by Inferen exercife, is exhaulted by continued motion, is remova-

ted by reft.
2. The multiplicity of the causes by which the experiments of galvanism are liable to be influenced to fuccess or failure, is so great, that we cannot, as yet, be too cautious in either rejecting or believing these accounts which we hear of the success of any such experiments; unless when we are able accurately to appreciate all the influencing circumstances.

3. This is remarkably confirmed by a fact, which the committee have related in their paper, and which respects the continuation of the galvanic spasm.

The communicator being supported by the hand, and refting, feemingly, without change of polition, still upon the same point of contact, there is known to take place a real change in the galvanic contact, although the communicator have remained thus apparently mo-

From this, it may be farther inferred, that the smallest possible change in the relative fituations of the parts of the galvanic circle and the excitatory arc, is capable of producing an effect upon the susceptible animal, and of occasioning mistakes in regard to the success of the experiment, if the utmost care be not taken to notice and estimate every variation that can hap-

4. The truth of the foregoing proposition is farther confirmed by the experiments upon the manner in which the galvanic movements are affected by the advancing or the withdrawing of the communicator. For these experiments fully evince the necessity for the most vigilant observation of every movement in the process of an experiment, not only collectively, but in their fuccession, and at the different periods of the operation.

5. It should seem that there are, in the formation of the excitatory arc, independently of its modes of acting in the galvanic operations, certain enervating, and certain exciting dispositions; of which some not only augment or diminish the energy in the present instance, but, besides, dispose the animal to a greater or a smaller fusceptibility, under subsequent experiments.

6. In order to accuracy of experiment, and to the correct ascertaining of the effects of an experiment, it is of great importance to know the precise state of the animal, the manner in which it has been preserved and fustained to the present moment, the state of the atmosphere, particularly as it is indicated by the hygrometer, by the barometer, the thermometer, and the electrometer.

7. It were to be wished, that in making a statement of experiments of different forts, these should be arranged in the order of their efficacy, and that there might thus be formed a galvanic scale, which should help us to determine the precife degree of the galvanic fusceptibility

Experidifferent from the arcs.

fusceptibility of any animal in this or that particular flate or polition, should direct us in subjecting every fuch animal only to experiments fuitable to its particular susceptibility; should enable us to estimate, from the efficacy or inessicacy of our experiments, the galvanic value of the circumstances in which we every day find ourselves, and should enable us to judge when the succels or miscarriage of an experiment can afford room for certain conclusions absolutely negative or affirma-

IV. In their experiments upon the means of varying, diminishing, and renewing the susceptibility of animal bodies to the influence of galvanism, the committee exaepti-mined, 1st, the influence of electricity upon that sufceptibility; 2d, the effects of the muscular organs, and of certain liquors, fuch as alcohol, the oxygenated muriatic acid, the folutions of potash and opinm, upon the galvanic properties; 3d, and at the medical school of Paris they made a number of experiments, in order to afcertain what new modifications the galvanic energy undergoes in various cases of suffocation or asphyxia. These last-mentioned experiments were made upon hotblooded animals, of which some were reduced into the state of asphyxia by submersion, some by strangulation, some by the action of gases, while others were killed in vacuo by the discharge of the electric spark. In that fuffocation which was produced by fulphurated hydrogenous gas, by carbonic vapours, and by submersion, in which the animal was suspended by the hinder feet, the gal-vanic susceptibility was entirely destroyed. The galvanic susceptibility was only suspended by suffocation produced by the pure carbonic acid confined under mercury. It was diminished, but not destroyed, in those cases of suffocation, which were occasioned by fulphurated hydrogenous gas that had loft a portion of its sulphur, by gas ammoniac, gas azote, or such gases as had been exhausted of their pure air by respiration; and the same thing was found to take place in animals which had perished by total submersion. But the galvanic susceptibility survived unaltered in suffocations brought on by fubmersion in mercury, by pure hydrogenous gas, by carbonated hydrogenous gas, by oxygenated muriatic acid, by fulphureous acid; as also when the fuffocation was occasioned by strangulation, by the abstraction of the air in the air-pump, or by discharges from an electrical battery. The results of the experiments at the medical school suggested the following reflections:

1. Though it be true that all cases of suffocation re-Rations femble one another in the privation of respirable air, and in the suspension of the functions of respiration, and of the circulation of the blood; yet, in their other circumstances, they are subject to great differences, a. rifing from diverfity of nature in the substances by

which they are occasioned.

2. Of these causes, some appear to act with a more thorough efficacy, penetrating at once all parts of the nervous and muscular systems. Others again seem to act but superficially, producing only pulmonary asphyxia, with its immediate effects.

SUPPL. VOL. I. Part II.

3. One of the most remarkable changes not confined to the organs of respiration, consists in the alterations produced on the galvanic susceptibility. In that respect the various cases of asphyxia differ greatly one from another.

4. The state of the irritability of the muscles, when examined by means of bodies, the mechanical action of which causes the muscles to contract by irritating them, is far from always corresponding to the state of their

galvanic fusceptibility.

5. Laftly, the causes of suffocation or asphyxia, do not act upon all parts of the muscular system in the same manner; but the heart is very often found in a state extremely different from that of the other muscles.

V. The comparison between the phanomena of galva-Comparinism and those of electricity is perhaps one of the most fon of the interesting objects of attention in the whole body of a-phenomena nimal physiology. Is is well known that Galvani was of galvaaccidentally led to his discovery by observing the mo nism with those of etions of some frogs, at a certain distance from an elec-lectricity. trical machine discharging sparks. The committee from the institute made, therefore, some attempts to ascertain the relations between electricity and galvanism. Having first paid due attention to the susceptibility of animals toward the influence of electricity, they then fought to discover to what precise degree animals divested of the natural covering of the epidermis were liable to be affected by the variations of the electrical fluid in the atmosphere around them. Next, comparing the susceptibility of electricity with the susceptibility of galvanism, they perceived that quantities of the electrical fluid, fuch as are still capable of being very accurately measured by the electrometer, are, however, often too weak to act upon a frog that retains the most perfect fensibility to all the energy of galvanism. members of the committee purpole to profecute farther their experiments upon this part of the subject.

VI. The following are the general refults of the ex Refults of periments made by M. Humboldt in the presence of some expethe committee:

1. There is no truth in the affertion of certain phy-Humbolds. fiologists, that the experiments of galvanism fail when tried upon the heart and those other muscles of which the contractions depend not upon volition; for these organs have been found to be actually subject to the influence of galvanism (D).

2. The effects of galvanism are liable to be interrupted by the confriction of a nerve, whenever both the nerve and the constricting ligature are enveloped in

the flesh of the animal body (E).

3. The powers of the exciting arc may be renovated or destroyed, even though its supporters remain the fame, and although the extremities of the arc be unchanged. Only the relations of the intermediate matters require to be altered.

4. There are atmospheres of galvanism.

5. There are substances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvanism.

M. Humboldt had performed also other experiments, 4 R which,

(D) This was demonstrated fix years ago by Dr Fowler.

⁽E) Dr Valli made this observation soon after the discovery of galvanism.

Effects of

galvanism

of the or-

gans of fenfe.

which, when he attempted to repeat them before the committee, could not be brought to fucceed, on account, as was supposed, of the season of the year.

Such are the principal refults of this valuable train of experiments upon galvanism. From them, our readers will perceive that this interesting subject is still very imperfectly understood, and will form some idea of the importance of the discoveries which a diligent profecution of it promifes to the philosopher and the physician.

The effects of galvanism upon some of the organs of fense are no less striking than those which we have seen

it capable of producing upon the muscles.

upon fome If the upper and under furfaces of the tongue be coated with two different metals, and these be brought into contact with each other, a peculiar sensation, refembling tafte, is produced in the tongue the moment that the metals touch each other. With the greater number of metals this fenfation is fcarcely perceptible; but with zinc and gold, zinc and filver, or zinc and molybdena, it is very strong and disagreeable. Fowler thinks it is ftrongest with zinc and gold; to us it appears a good deal stronger with zinc and silver. It is fenfibly stronger when the zinc is applied to the upper, and the filver to the under furface of the tongue, than when this order is inverted. The sensation is most distinct when the tongue is of the ordinary temperature, and the metals of the same temperature with the tongue. Any considerable increase or diminution of heat in either greatly lessens the effect. Mr Subsir of Berlin, in his Theorie des Plaisers, p. 155 (published in 1767), takes notice of the disagreeable taste produced by silver and lead in contact upon the tongue. This is the first instance of galvanism that has been made public.

To ensure complete success to the experiment, the metals ought to be allowed to remain some time in contact with the tongue before they are made to touch each other, that the tafte of the metals themselves may not be confounded with the fensation produced by their mere contact. Whatever has a tendency to blunt the fensibility of the tongue, as opium, alcohol, acids, and

the like, diminishes the effect of the metals.

It is difficult to describe the sensation thus produced accurately. It has been called fubacid; but we think it more nearly refembles the effect produced by allowing a grain or two of nitre to lie upon the tongue for fome time, than any other tafte with which we are acquainted. Joined to this, there is evidently a metallic rafte, which varies with the metal employed; but we are inclined to confider this as the ordinary effect of the metals upon the tongue, which cannot be perfectly diffinguished from that occasioned by their mutual con-

This taste can also be produced by applying one of the metals to the tongue, and the other to any part of the Schneiderian membrane. Professor Robison has made many experiments of this kind, the refult of which is contained in a letter to Dr Fowler. "I find (fays he), that if a piece of zinc be applied to the tongue, and be in contact with a piece of filver which touches any part of the lining of-the mouth, nostrils, ear, urethra, or anus, the fenfation refembling tafte is felt on the tongue. If the experiment be inverted, by applying the filver to the tongue, the irritation produced by the zinc is not fenfible, except in the mouth and the

urethra, and is very flight. I find the irritation by the zinc strongest when the contact is very slight, and confined to a narrow space, and when the contact of the filver is very extensive, as when the tongue is applied to the cavity of a filver spoon. When the zinc touches in an extensive surface, the irritation produced by a narrow contact of the filver is very diffinct, especially on the upper fide of the tongue, and along its margin. This irritation feems to be mere pungency, without any refemblance to taste, and it leaves a lasting impression like that made by caustic alkali.

"When a rod of zinc, and one of filver, are applied to the roof of the mouth, as far back as possible, the irritations produced by bringing their outer ends into contact are very strong, and that by the zinc refembles taste in the same manner as when applied to the tongue."

M. Volta found, that when a tin cup, filled with an alkaline liquor, is held in one or both hands previously moistened with water, if the point of the tongue is dipped in the liquor, an acid taste is perceived. This is at first distinct and pretty strong, but gradually yields to the alkaline tafte of the liquor. The acid tafte is still more remarkable, when, instead of an alkaline liquor, an infipid mucilage is made use of. The same philosopher found, that when a cup made of tin, or what is better, of zinc, was filled with water, and placed upon a filver support, if the point of the tongue was applied to the water, it was found quite infipid, till he laid hold of the filver support, with the hand well moistened, when a very distinct and very strong acid taste was immediately perceived.

If one of the metals be applied to the tongue, and the other to the ball of the eye, a pale luminous flash is perceived when they are brought into contact with each other, and the fenfation refembling taste is at the same time produced in the tongue. A flash is, in like manner, produced when one of the metals is applied to the eye, and the other to any part of the palate, fauces, or infide of the cheek. This experiment requires a good deal of attention in the performance; care must be taken not to press the piece of metal against the ball of the eye, lest a stash should be produced by the mere mechanical pressure. It should be cautiously introduced between the eye lids, till it just touch any part of the ball; and it should be allowed to remain in that situation for some time before it is brought into contact with the other piece of metal, that the parts may be fo far accustomed to it as to admit of the fensations produced being properly attended to. The experiment fucceeds very well with tin and filver; but the flash is more bright when zinc and gold are used. The piece of metal which is applied to the ball of the eye must be finely polifhed, otherwife the mechanical irritation is fometimes fo great as to prevent the flash from being perceived. Dr Robifon has observed, that the brightness of the flash corresponds with the extent of contact of the metal with the tongue, palate, fauces, or cheek.

If a piece of one of the metals be placed as high up as possible between the gums and the upper lip, and the other in a fimilar fituation with respect to the under lip, a very vivid flash of light is observed at the moment that they are brought into contact, and another at the instant of their separation. While they re-

main in contact, no flash is observed.

When a rod of filver is thrust as far as possible up

one of the nostrils, and then brought into contact with a piece of zinc placed upon the tongue, a very strong slash of light is produced in the corresponding eye at the instant of contact. We have sometimes imagined, that the slash in this experiment was produced before the metals actually touched; but in this we may have been decrived.

The following curious experiment was first made by Professor Robiton: "Put a plate of zinc into one cheek, and a plate of filver (a crown piece) into the other, at a little distance from each other. Apply the cheeks to them as extensively as possible. Thrust in a rod of zinc between the zinc and the check, and a rod of filver between the filver and the other cheek. Bring their outer ends flowly into contact, and a fmart convullive twitch will be felt in the parts of the gums fituated between them, accompanied by bright flashes in the eyes. And these will be distinctly perceived before contact, and a fecond time on feparating the ends of the rods, or when they have again attained what may be called the striking distance. If the rods be alternated, no effect whatever is produced."-The flashes produced in this last experiment are rather more vivid than any which we have been able to excite by the other methods. The convultive twitches are very diffinct, and fomewhat painful, but quite different from the fenfation produced by an electric shock. If the edges of the tongue be allowed to touch the plates of metal in the cheeks, the fenfation refembling tafte is felt very firongly; but this does not in the least impair the other effects of the experiment.

No method has yet, we believe, been discovered of applying the galvanic influence so as to affect the senses of smelling or hearing. We have tried many experiments with this view, chiefly on the organs of smelling but hitherto without any success(F). Neither has the sense of touch been affected by it, unless, indeed, the following experiment be considered in that view: Let a small portion of the cuticle be removed from any part of the body by a sharp knife, and carry the incision to such a depth that the blood shall just begin to ooze from the cutis vera. Let a piece of zinc be applied here, and a piece of silver to the tongue; when they are brought into contact, a very smart irritation will be felt at the wound.

Some very fingular facts of this kind have been discovered by M. Humboldt, who had the refolution to make himfelf the fubject of many well-devised experiments. One of the most remarkable of these is the following: He caused two blistering plasters to be applied on the deltoid muscle of both his own shoulders. When the left blister was opened, a liquor flowed out, which left no other appearance on the skin than a slight varnish, which disappeared by washing. The wound was afterwards left to dry up: this precaution was necessary, in order that the acrid humour which the galvanic irri-

tation would produce, might not be attributed to the idiofyncrifis of the veffels. This painful operation was fearcely commenced on the wound, by the application of zinc and filver, before the ferous humour was difcharged in abundance; its colour became visibly dark in a few feconds, and left on the parts of the skin where it passed traces of a brown inslamed red. This humour having descended towards the pit of the stomach, and stopped there, caused a redness of more than an inch in furface. The humour, when traced along the epidermis, left stains, which, after having been washed, appeared of a bluish red. The inflamed places having been imprudently washed with cold water, increased so much in colour and extent, that M. Humboldt, as well as his physician Dr Schalleru, who affisted at these experiments, entertained fome apprehension for the confequences.

Having now taken notice of the principal facts that are hitherto known in galvanism, we proceed to confider some of the leading opinions on the subject.

The first writers upon the discovery of Galvani seem Phenomena almost univerfally to have taken it for granted, that the of galvaphenomena depend on the electric fluid; and leaving this nifm fupvery important question behind them, proceeded to exposed to re-plain how this sluid produces such effects. The celebrated lectricity; discoverer of this influence himself considers a muscle as the perfect prototype of a Leyden phial. When a muscle contracts upon a connection being formed, by means of one or more metals between its external furface and the nerve which penetrates it, M. Galvani contends, that, previously to this effect, the inner and outer parts of the muscle contain different quantities of the electric fluid; that the nerve is confequently in the fame state, with respect to that sluid, as the internal substance of the muscle; and that, upon the application of one or more metals between its outer furface and the nerve, an electrical discharge takes place, which is the cause of the contraction of the muscle. Thus the nerve is supposed to perform the office of the wire connected with the internal furface of the phial; and the excitatory arc is confidered merely as a conductor.

This theory appears to us just as incapable of explaining the phenomena of galvanism as it is inconsistent with the known laws which regulate the motions of the electric shuid. We shall not consider it minutely; for we hope it will soon appear highly probable, if not certain, that the electric shuid has no share in the production of the phenomena in question. If this be the case, all the different modifications of that theory must of course fall to the ground. At present we shall content ourselves with asking the following questions:

1. How is it possible for the electric sluid to be con-This suppodensed in a muscle, which is wholly surrounded by sub-sition ill stances capable of conducting that sluid?

2. If we suppose there is some non-descript non-conducting substance placed between the external and in-

(F) Professor Robison has long ago observed, that the slavour of a pinch of snuff taken from a box made of tin-plate, which has been long in use, so that the tin coating is removed in many places, is extremely different from that of snuff when taken from a new box, or a box lined with tinfoil. The same difference is observed when we rub a piece of pure tin, or of pure iron and a half worn tinned plate, with the singer. Also, if we rub a cast steel razor, and a common table knife consisting of iron and steel welded together. This is surely owing to a cause of the same kind.

ternal parts of a muscle, which may admit of the one being positively, and the other negatively electrified at the same time; how comes it to pass that a discharge does not take place, and a consequent contraction ensue, when any substance whatever, capable of conducting the electric sluid, is interposed between the nerve and the external surface of the muscle? For example, when the nerve and muscle are laid bare, and the animal thrown into water; or when the nerve is cut through, and the end applied to the external surface of the muscles.

3. How does it happen, when one discharge actual ly takes place, in consequence of the application of the excitatory arc, that the balance is not instantly restored? That this does not happen, appears by the same muscle and nerve being capable of producing many hundreds of similar, and equally strong discharges, without any apparent means of the equilibrium being again disturbed.

We have never feen any answers to these questions which appeared to us at all satisfactory; and till we have seen them answered, we must be excused for disbe-

lieving M. Galvani's theory.

One of the earliest writers, and one of the most affiduous investigators of the phenomena of galvanism, is Dr Valli. He differs in opinion from Galvani upon several points; but agrees with him in thinking electricity and galvanism the same. Let us consider the proofs by which he supports this doctrine.

"I have afferted (fays he), that the nervous fluid is the fame with electricity, and with good reason; for

Proofs by which Valli "Substances which conduct electricity are conductors endeavour, likewife of the nervous sluid.

"Substances which are not conductors of electricity do not conduct the nervous fluid.

"Non-conducting bodies, which acquire by heat the property of conducting electricity, preferve it likewife for the nervous fluid.

"Cold, at a certain degree, renders water a non-conductor of electricity as well as of the nervous fluid.

"The velocity of the nervous fluid is, as far as we can calculate, the fame with that of electricity.

"The obflacles which the nerves, under certain circumflances, oppose to electricity, they present likewise

to the nervous fluid.

"Attraction is a property of the electric fluid, and this attraction has been discovered in the nervous fluid.

"We here fee the greatest analogy between these sluids; nay, I may even add, the characters of their

identity."

That there is a confiderable analogy between fome of the effects of the electric fluid and fome of the phenomena of galvanism, we readily admit; but that "the characters of their identity" are anywhere to be found, we absolutely deny. In the above passage, Dr Valli confiders it as certain, that the nervous fluid is the cause of the phenomena discovered by Galvani. But it has never been demonstrated irrefragably, that any such thing as a nervous fluid exists, and still less that this is the same with the influence discovered by Galvani.

That bodies are, in general, conductors or non conductors of galvanism, according as they are conductors or non conductors of electricity, we believe to be true: but this rule is by no means without exception, as it certainly would be, if galvanism and electricity were the

fame. There is an experiment of Dr Fowler's, which feems to flew, that water is a more powerful conductor of galvanism than mercury; though the reverse is

generally allowed as to electricity.

If the abdomen of a frog be filled with water, and a filver probe passed through it so as to touch the sciatic nerves no contractions are produced; neither do they appear when the probe is touched above the surface of the water with a piece of zinc. But if the zinc be applied to the probe at the surface of the water, contractions are produced as vigorous as if both the metals touched the nerve. Here the water serves as a conducting medium between the nerves and the point where the metals touch each other: but if the abdomen be silled with mercury instead of water, no contractions are produced by applying the silver probe to the nerves, and touching the probe with the zinc at the surface of the mercury. We do not see how this experiment can be accounted for, except by allowing that water is a more powerful conductor of galvanism than mercury.

more powerful conductor of galvanism than mercury.

If this experiment should be thought inconclusive, we have the authority of M. Humboldt, and of the committee of the National Institute of France, for saying, that there are substances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvanism. This is certainly sufficient to take away all weight from Dr Valli's two first reasons for considering these two sluids as the same, viz. that all conductors of electricity are likewise conductors of galvanism; and that all bodies which do not conduct the former are also non conductors of the latter. These two are by far the most important of his reasons; and if they were true in their sufficient, they would certainly shew a very striking analogy, though they would by no means deserve the appellation of "characters of identity."

As to the Doctor's two next propositions, which regard the effects of heat and cold in rendering bodies conductors or non-conductors, they are, in fact, only branches of the two first; and as we have seen that these are not univerfally true, we might admit that they are correct in this particular, without weakening our argument. For this reason we shall not consider them minutely; but we may observe that Dr Fowler's experiments shew, that boiling water, and water cooled down to the freezing point, both conduct this influence as well as water at the ordinary temperature of the atmosphere. If any change in the conducting power takes place beyond these points, it may with greater probability be ascribed to the changes of form which the water undergoes, than to the increase or diminution of its temperature.

We confess ourselves perfectly ignorant of any data upon which Dr Valli could found a calculation, the result of which could shew that the velocity of the nervous fluid is the same with that of electricity. Suppose we should take it into our heads to affert that the velocity of galvanism is the same with that of light, we apprehend our author could not easily demonstrate the contrary. Neither, in all probability, would he consider this affertion of ours as a tufficient proof that galvanism

and light are the faine.

With regard to the next proposition, that "the obflactes which the nerves, under certain circumstances, oppose to electricity, they present likewise to the nervous fluid;" we may remark, that any obstacle which

Proofs by which Valli endeavours to support it,

Inconclutive and

2

deftroy

destroys the functions of a nerve completely, will prevent the muscles which are supplied by that nerve from contracting upon the application of any stimulus whatever (G). It does not, however, by any means follow, that the passage of either the galvanic or the electric shuid is prevented. The nerves may still be very good conductors of both, though the muscle is deprived of all power of contracting. That there are obstacles, however, which the nerves, under certain circumstances, prefent to the passage of electricity, but which they do not under the same circumstances present to galvanism, we think abundantly demonstrated by Dr Valli's own experiments.

"I have frequently observed (fays he) that the legs, of which the nerves had been tied at a certain distance xperi-from the muscles, did not feel the action of a certain quantity of artificial electricity, although they were violently convulfed by exciting that which was inherent and peculiar to them." What then was the cause of the difference observed in these cases between the effects of galvanism and electricity? Was it, that the quantity or degree of the former exceeded that of the latter?

Be it fo.

Dr Valli informs us, that in his experiments, an electric charge which could flash through a thickness of air equal to .035 of an inch, produced no movement in the leg of a frog of which the crural nerve was tied, while the other leg, of which the nerve was left free,

underwent confiderable movements.

That the influence discovered by Galvani can pass through an exceeding thin plate of air, is certain, as it is transmitted from link to link of a chain, where no confiderable force is used to bring the links into contact. Dr Robison's experiment, too, in which the flashes of light are distinctly observed before the rods of filver and zinc touch each other, is another proof of the fame fact; and, if we be not deceived, the fame thing takes place when a rod of filver thrust up the nostril is applied to a piece of zinc in contact with the tongue. But that it will only pass through an exceeding thin plate of air, any man may convince himself by an experiment, first tried by Dr Fowler, which is easily repeated. If a flick of fealing wax be coated with tinfoil, it will be found a very good conductor; but if, with a sharp pen knife, an almost imperceptible division be made across the tiufoil, even this interruption of continuity in the conductor will be found sufficient effectually to bar the passage of galvanism.

We find, then, that a quantity of the electric fluid which can pass through a plate of air of the thickness of .c35 of an inch, is obstructed by a ligature upon a Herve, while the galvanic influence paffes readily along a nerve included in a ligature, but is obstructed completely by making an almost imperceptible division in a good conductor. 'The plate of air in this cafe furely' is not near .035 of an inch in thickness. It results incontestibly, from a comparison of these two experiments, that there is, between these two agents, some other difference besides the mere degree of intensity.

We come now to the last reason which our author

assigns for his belief that galvanism, or, as he chooses to call it, the nervous fluid, is the same with electricity. It will be found a very important one. That property by which bodies charged with the electric fluid attract or repel other bodies, according as they are in the same or the opposite state of electricity from themselves, is so striking, and at the same time so universal, that it has been very properly adopted as the measure of this fluid. If it were true, then, that the galvanic influence poffessed the same properties of attraction and repulsion as the electric fluid, this circumstance would certainly increase the analogy between them very much. As we have already feen, however, that they differ in other effential points, even if it were true that they agreed in this, it could constitute no proof of their identity. But if, on the other hand, we should find, that this affertion of our author is founded on error, and that the galvanic influence possesses in no degree whatever those properties of attraction and repulsion which have always been justly confidered as effential characteristics of the electric fluid, we shall then be fully justified in afferting, that thefe two agents, however much they may resemble each other in some less important particulars, are in their nature totally distinct and unconnected.

Let us examine the proofs by which Dr Valli's af-And with fertion is supported. He tells us, that he observed the the know. hairs of a mouse, attached to the nerves of frogs, by ledge of ea the tinfoil with which he furrounded them, alternately lectricity. attracted and repelled by each other, whenever another metal was so applied as to excite contractions in the frogs. We are very far from meaning to infinuate that 1)r Valli did not fee, or think he faw, what he thus defcribes; but that the motion of the hairs must have arisen from some cause, different from that to which he ascribed it, cannot admit of a doubt; for hairs, in such a state of electricity as he supposes, never attract, but

always repel each other.

Dr Fowler, who has paid particular attention to this part of his subject, has many times repeated this experiment, both in the manner described by Dr Valli and with every variation in the disposition of the hairs which he could devife: but whether they were placed on the metals, the nerves, or the muscles, or upon all at the fame time, he has never in any instance been able to obferve them agitated in the flightest degree. He has made similar experiments upon a dog, and upon a large and lively skate, by disposing, in the same way that Valli did the hairs of a mouse, flakes of the finest flax, swandown, and gold leaf: but although the contractions produced in the skate, by the contact of the metals, were fo strong as to make the animal bound from the table, not the least appearance of electricity was indica-He next suspended from a slick of glass, fixed in the ceiling of a close room, some threads, five feet in length, of the flax used in the former experiment; and brought fome frogs recently killed, and infulated upon glass, as near to them as possible without touching: but the threads were in no wife affected by the contractions produced in the frogs.

In a very ingenious paper upon galvanism by Dr

(G) We do not here mean that contraction which muscles are susceptible of long after death, upon having their fibres mechanically irritated, which is produced by what physiologists have called the vis insita, and which is perfeetly known to our cooks, as it was to their predecessors in the Roman kitchens, as the foundation of the art of crimping. We at present confine ourselves to contraction produced through the medium of the nerves.

Reafoning Wells on the fame fubject,

Wells, which is published in the London Philosophical Transactions for 1795, that gentleman maintains the opinion, that the influence discovered by Galvani is electrical. He admits, that it is not attended with those appearances of attraction and repulsion which are held to be the tests of the presence of electricity; but he contends, that " neither ought figns of attraction and repulsion to be in this case presented on the supposition that the influence is electrical; fince it is necessary, for the exhibition of fuch appearances, that bodies, after becoming electrical, should remain fo during some sensible portion of time; it being well known, for example, that the passage of the charge of a Leyden phial, from one of its furfaces to the other, does not affect the most delicate electrometer, suspended from a wire, or other substance, which forms the communication between them."

Inconclufive likewife.

That the charge of a Leyden phial does not, in paffing along a wire, affect an electrometer, is certain; and it is equally true, that we have no means of applying an electrometer to a quantity of galvanism in a state of rest in a body. If this influence ever exists in such a flate, we have no test by which we can discover its prefence; and it is only from the effects which it produces in transitu that we know of its existence. But the electric fluid, in passing from link to link of a chain, sensibly affects an electrometer; and in Dr Fowler's experiment with the skate, for example, as more than one piece of metal is employed as an exciter, the fluid, in passing from one piece to another, should have affected the light fubstances which were placed upon them. This appears to us a sufficient answer to the objection started by Dr Wells: but the same objection having been lately made to us by a gentleman from whom we shall always receive every fuggestion with uncommon deference, we thought it worth while to try the following experi-

Three hours after a frog had been decapitated, it shewed strong signs of galvanic susceptibility. One of the sciatic nerves being coated with tinfoil in the usual manner, the leg was laid upon a plate of zinc. A gentleman was defired to lay hold of the nerve and its coating with the fingers of one hand, which had been previously dipped in water, while with the other hand, also wet, he held the end of a small brass chain about two inches in length. Another gentleman now took hold of the other end of the chain, and with a filver probe, held in his other hand, touched the plate of zinc. The influence being thus made to pass through the chain, the leg contracted vigorously; but a very sensible electrometer, held fo near to the chain as almost to touch it, was neither attracted nor repelled. In performing this experiment, it was necessary to have the hands wet, as the dry cuticle tends much to obstruct the passage of galvanism; but the utmost care was taken that the chain should be perfectly dry, otherwise the influence might have been transmitted by the moisture upon its surface without paffing through the chain itself.

To avoid the possibility of this happening, the experiment was varied in the following manner: The frog's leg was laid upon a plate of zinc, and the nerve upon a plate of filver. A gentleman now took a filver probe, and one end of the brass chain in contact with it, in one hand; and in the other hand he held the other end of the chain in contact with a rod of zinc. He now touched the filver plate with the rod of filver, and the zinc plate with the rod of zinc. As the influence was not now to be made to pass through his body, there was no necessity for his hands being wet; the whole excitatory arc was therefore made completely dry. In this way very strong contractions were excited in the leg, and still the electrometer was not affected in the fmallest degree when brought near the chain

It is proper to observe, that Dr Valli, in his affertion that attraction is a property of galvanism, does not rest entirely upon his own observation; a committee of the Academy of Sciences at Paris performed the following experiment along with him: "They placed a prepared frog in a vessel which contained the electrometer of M. Coulomb, charged negatively and politively by turns. In both cases, in exciting the animal in the common way, the ball of the electrometer was attracted." It appears to us that Dr Valli and the committee have been deceived, by the friction produced by the motion of the animals under their experiments having excited fo much electricity as to affect the electrometer. The first time we tried the experiment abovementioned with the brass chain, we were almost misled by a similar circumstance. Instead of an artificial electrometer, which we happened not to have at hand, we made use of a very long and slender human hair; and we found that it was strongly attracted by the chain. Upon an attentive examination, however, we found that this did not arise from the action of the influence paffing thro' the chain, but from the flate of the hair itself, which was forhighly electrical as to be strongly attracted by every conducting substance which it approached. Upon substituting another hair, which shewed no mark of being either positively or negatively electrified, it was neither attracted nor repelled by the chain. From the above, or fome similar circumstance, it is probable that Dr Valli's mistake has originated; but we are consident, that whoever will repeat the experiment with fufficient attention, will find the refult precifely as we have deferibed it.

Perhaps it may still be faid, that although we have never been able to discover attraction and repulsion as properties of galvanism, this may arise from our not being able to accumulate this influence in sufficient quantity. To this reasoning, if reasoning it can be called, we oppose the following considerations, which tion, that state a diffimilarity in the phenomena of electricity and the phenogalvanism, that feems absolutely irreconciliable with the mena of idendity of the cause.

Nothing is more completely established in the science and of electricity than this that all these are of electricity than this, that all those appearances which fult not we call attradions, repulsions, abstradions, and acumula-from the tion of electric fluid, are precisely similar to what would same cause be the appearances, if electricity were a sluid, whose particles repel each other, and attract the particles of other matter, according to a certain law (See ELEC-TRICITY, Suppl.). Of all those phenomena, the most remarkable is the accumulation of electric energy (to give it no more definite name), by means of thin idioelectrics, coated with non-electrics; fuch, namely, as are exhibited by the Leyden phial, the condenfer, the

If the phenomena of galvanism are produced by the passage of electric fluid from one extremity of the excitatory are to the other, this passage will be regulated by the known laws of electricity. It may therefore be-

accumulated (in transitu) by means of an apparatus similar to the coated pane, or to the condenser. Professor Robison, with this view, made the following experiments.

1. He made a part of the conductor to his condenfer, or collector of atmospheric electricity, consult of a long glass rod, on one fide of which was fastened (with varnish) a very narrow slip of tinfoil; there was a fine point at one end of this rod, and a gold leaf electrometer at the other. This apparatus was infulated at one end of a room 19 feet long, having a window in the middle of each fide. A finall electric machine was placed at the other end. On a dry day, with a gentle breeze in a direction across the room, both windows were opened a little way, fo that there was a continual stream of air across the room. The machine was worked; and after a short time had elapfed, the electrometer began to diverge, gradually opened, and at last struck the conducting slips on each side, and then collapsed, and again began to diverge. The windows were thut; and immediately, without working the machine, the electrometer diverged rapidly, and touched the fides of the phial every minute and half. This continued fo long, that there feemed to be no end to it. The Profesfor now made a cut across the tinfoil with a very sharp knife; the electrometer now diverged very feebly, and 71 minutes elapsed before it touched the fides. He passed the knife a second time through the cut. This widened it (though scarcely fensible to the eye), because the knife had been blunted by the glass in the first operation. All divergency of the electrometer was now at an end; and although the machine was worked till the electric finell was fenfible at the door to a person who happened to come in at this time, no tendency to divergence was observed. (N. B. the top of the electrometer had no conducting Inbstance about it, except the slip of tinfoil).

The cut, being examined with a microscope furnished with a micrometer, was $\frac{1}{10000}$ th of an inch. It was now filled up, by binding over it another slip of tinfoil. A plate of tale, whose thickness did not exceed the 900th of an inch, was coated on one side in a circle of $1\frac{1}{2}$ inch diameter. The electrometer was removed, and the coated side of the tale was put into close contact with the slip of tinfoil on the glass rod. A stand of tin, whose top was a plate of $1\frac{1}{2}$ inch diameter, smeared over with mercury, was placed in contact with the other side of the tale, and they were pressed into

very close and continuous contact.

The machine being now worked, the coated talc received a charge in about 5 minutes sufficient to give a very smart shock: and this was repeated with great regularity every five or fix minutes. The windows were now thrown open, and the room cleared of its former contents of air, till none of those present could perceive any electric smell. The machine was now worked again. But after half an hour, only a very faint twitch was self; but enough to shew that an accumulation was taking place. The windows were

now half shut. After working the machine about sive minutes, a faint twitch was obtained; after a quarter of an hour more, there was a moderate shock.

In this state of things, the apparatus was examined as a condenser, by first taking out the sharp point by an insulating handle, and then removing the tin stand. Examined in this way, it appeared plainly that, even when all the windows were open, the accumulation began almost as soon as the machine was worked. Nay, it was found, on another day equally savourable, that a plate of tale $\frac{47}{1000}$ or $\frac{50}{1000}$ of an inch thick, took a charge, although a cut of $\frac{11}{10000}$ wide did not allow the electricity to fly across it. This is perfectly similar to all our experiments on coated glass. The thickness which admits an accumulation is almost incomparably greater than the distance to which a spark will fly, or a concussion is producible, in the same intensity of electricity.

2. The above described apparatus was infulated, and a wire connected with each end. To one wire was joined a thin plate of lac, coated on the fide next the wire; and to the other a piece of moist leather covered with tin-foil. These plates were rubbed together by means of infulating handles. The plate of coated tale quickly

took a charge.

The fame plate of tale, and afterwards another plate not more than half as thick, was now made part of the excitatory are, and fometimes part of the animal arc. Sometimes plates of varnish, incomparably thinner than either of these, were employed. But all Professor Robison's attempts to produce an accumulation of galvanic energy in this way were fruitless. The second form of the electrical experiment was adopted, as having a somewhat greater resemblance to the supposed procedure of galvanism; but the well-informed electrician will easily perceive, that the first form is far more delicate and decisive.

The internal procedure in the electric and galvanic convultions is therefore fo different, nay, opposite, that we cannot bring ourselves to think that the appearances

are operations of the fame agent (H).

We have now gone over all the points of refemblance which, in Dr Valli's opinion, constitute the characters of the identity of galvanism and electricity. We think that, without going farther, we might safely rest our affertion, that these two agents are perfectly distinct and unconnected with each other. But there are several other circumstances which merit attention.

No electrical phenomenon can take place between Farther two bodies, unless these bodies be in opposite states of confidera-electricity with regard to each other. Now, how are tions on ewe to account for the accumulation of electricity in any lectricity body, or part of a body, surrounded on all hands by and galva-conducting substances? The experiments of Galvani succeed equally well, whether the subjects of them be insulated or surrounded by conductors; whether performed in the driest air or under water (1); whether, by means of an electrical machine, we charge the animal and the metals till every part of them strongly affect

(H) What if it were called metallorgasm, which translates exactly metallic irritation, or metallegerssim, from

⁽¹⁾ Dr Fowler mentions an exception to this. "When the feparated leg of a frog was held under water, and formed part of the circuit through which this influence had to pass in order to excite another leg, it never contracted; although it did, and strongly, when held above the surface." In this case it is plain, that the frog's

the electrometer, or whether we reverse the experiment and electrify them negatively, still no change is produced in the force or frequency of the actions excited by the application of the metals. Is there any electrical experiment which could continue to give the same result in such opposite circumstances? or is there any possibility of accounting for it consistently with the known laws of the electric stuid?

The writers on this subject who adopt the electric theory, instead of attempting to explain how the electric fluid can be condenfed in a body furrounded by conducting fubstances, have recourse to the analogy of the gymnotus, torpedo, and other fishes of the same kind. Here, say they, we have in fact the electric sluid aceu mulated in fuch a fituation, and there is no reasoning against facts. We answer, that these animals are all furnished with organs of a very peculiar structure, which may possibly be fitted for the purpose of such a condenfation. Besides, we apprehend it has never been in-contestibly proved that these singular animals derive their powers from the electric fluid. Without wishing to enter into this question, which is foreign to our prefent subject, we may remark, that Mr Walsh discovered, that the shock of the torpedo would not pass through a fmall brass chain; a circumstance in which it differs remarkably both from electricity and from the influence discovered by Galvani.

It were worth while to try Professor Robison's methods of accumulation in the examination of the convulsions occasioned by the torpedo. The Professor suffects that the popular horror at the lamprey, and the accounts of cramps and pains produced by it, have their source in some similar powers of that animal.

Dr Valli's reasoning on this part of the subject is very curious. He takes it for granted that the gymnotus owes its influence to the electric stuid. Then, though the gymnotus gives shocks and emits sparks, while the torpedo only gives shocks without emitting sparks, he says it would be absurd to affert that the torpedo derives its influence from a cause different from the gymnotus. Again, though the influence discovered by Galvani neither gives shocks nor emits sparks, it would still be absurd to maintain that it is not the same as the electric sluid, and as the influence of the gymnotus and torpedo. To diffent from any part of this very logical deduction, he declares would be contrary to the laws of philosophising! Risum teneatis?

Afraid, probably, that his readers might be tempted to offend against these new laws, he proceeds to strengthen them by the analogy of animals and vegetables retaining an uniform temperature in media, warmer or colder than their own bodies; from which he argues that they may also have a power of accumulating electricity, and retaining it in a particular part, though their whole bo-

dies are conductors. But the cases are in no respect fimilar. Neither animals nor vegetables accumulate caloric in any particular part of their bodies in preference to any other part. They have no power of retaining caloric in their bodies more strongly than any other bodies do; for if they are placed in a medium colder than themselves, they are continually imparting caloric to that medium. Neither is there the smallest proof, from any experiments yet published, that when placed in a medium warmer than themselves, they do not eontinually absorb caloric from it. The existence of a frigorific power in animals appears to us exceedingly problematical; but if it were proved to exist, it would by no means demonstrate that animals or vegetables have a faculty of declining to abforb caloric from bodies warmer than themselves. It is readily admitted, that animals and vegetables have a power, within certain limits, of preserving their temperature higher than that of the furrounding medium; nor is there any thing furprifing in this, as the caloric, which they are continually receiving by the decomposition of oxygenous gas, is diffipated flowly. But if we should allow that animals have a fimilar faculty of generating the electric fluid; from the nature of that fluid it must be continually communicated, not only to every part of the bodies of the animals themselves, the whole of which are conductors, but to every conducting substance contiguous to them: and this must take place, not slowly, like the diffipation of ealoric, but inftantaneously, so as to render any sensible accumulation impossible.

Galvanism differs from electricity in nothing more Differe remarkably than in the mode of its excitement and dif-in their charge. To produce the phenomena discovered by Gal modeo vani, no operation at all fimilar to the friction of an e-citemen lectric upon a conducting fubstance is necessary (1). The nerves and muscles have only to be laid bare, and a communication formed between them by means of the excitatory arc, when the contractions immediately enfue. In the case of electricity, a single discharge having restored the equilibrium, no farther effects can be produced till this has been again destroyed by some means eapable of producing a condensation in one quarter, and a comparative rarefaction in another. The fact is very different with regard to galvanism; for with it the number of shocks which may be given appears to be infinite. Nay, they frequently become stronger in proportion as they have been longer continued: this influence differing extremely in this particular, too, from the electric fluid, which, besides being itself exhausted, never fails in a remarkable manner to exhaust the contractile power of the muscles.

The permanence of the effects of galvanism is still 30 more striking in the experiments upon the organ of And in taste. When the metals are applied to the tongue, the their calculation seeds.

leg had in fact formed no part of the circuit through which the influence passed; the influence had been transmitted by the water in which the leg was held.

⁽¹⁾ It is true, as we have noticed above, that galvanic energy is fometimes communicated to a conducting substance by rubbing it upon some other substance; but this has no resemblance to the excitement of electricity by friction. The galvanic energy is communicated in this case to a conducting substance, and it succeeds as readily when both the bodies are of this class as when one of them is an idio-electric. But no electric phenomenon has ever been produced by the friction of two conducting bodies upon each other; one of them must be an idio-electric, and it is in this one that the excitement takes place.

fensation produced is not sudden and transient; but so long as the metals are in contact with the tongue and with each other, fo long does the tafte continue; and, after some time, it becomes infufferably disagreeable. M. Volta, who adopts the electric theory with various modifications, fenfible of the permanence of the effect, in his curious experiments abovementioned supposes, that a stream of electricity passes from the tin cup to the liquor, from this to the tongue of the person making the experiment, then through his body, and returns through the water upon his hands to the cup; and thus he supposes the sluid to move perpetually in a circle. It is furely unnecessary for us to observe, that the supposition of a stream of electricity continually moving in a circle in this manner, is wholly inconfishent with the laws which appear in every case to regulate the motions of that sluid. The same observation applies to the manner in which he explains most of the other phenomena

of galvanism.

The electric fluid cannot be put in motion but by destroying the equilibrium to which it perpetually tends; but whenever this is destroyed, all that is required to produce a discharge is, that a single conducting fubitance be placed between the two points in which it is unequally distributed. Here again there is a very wide diffinction between this fluid and the influence discovered by Galvani. M Volta divides all conductors of galvanilin into two classes; 1st, Dry conductors, comprehending metals, pyrites, fome other minerals, and charcoal; and, 2d, Moist conductors. He afferts, that it is absolutely necessary, in order to the production of the phænomena, that two conductors of the first class touch each other immediately on one hand, while at their other extremities they touch conductors of the fecond class. Whether this be admitted or not, we have already flated our opinion that the action of two different substances is absolutely necesfary in order to excite contractions: and although it is contended by some writers that a fingle piece of metal has fometimes been found sufficient, yet even they must allow that, in by far the greater number of cases, it has been found necessary to make use of two metals, and that the effect is even heightened in general by employing three. In the whole science of electricity, we

SUPPL. VOL. 1. Part II.

do not know a fingle fact which bears the flightest analogy to this. Never in a fingle instance has it been found, that the effects of a Leyden phial have been increased by using a conductor formed of two or more metals in procuring the discharge.

Before leaving the subject of conductors, we may some men take notice of a very curious and important fact men-non-contioned by Dr Valli. " Amongst men," fays he, " there ductors of are some individuals who are good conductors, others galvanism.

who are less so; and some again who appear to be almost non-conductors. I was one day carrying on, with three of my friends, some experiments upon frogs. A frog was put in water, and we each by turn essayed its power. Two of us excited strong convulsions, the third only feeble oncs, and the fourth none at all. This experiment was repeated frequently with the fame refult. This is not the only example I could adduce of the reality of this fact, but I do not think it necessary to dwell any longer upon it." We have met with one individual who is not fensible of any peculiar fensation when the metals are applied to his tongue. This feems in some measure to corroborate Dr Valli's observation. It is apprehended, however, that all men are equally good conductors of electricity.

There is still another very marked distinction between the effects of galvanism and electricity. No shock at all resembling that produced by the electric fluid has ever been felt by any person whose body was made a part of the chain conducting the galvanic influence, while a very small quantity of the electric fluid is immediately felt (K). In Dr Robison's experiment with the plates of zinc and filver in the cheeks, there is no doubt a convulsive twitch distinctly felt in the gums; but, as we have already observed, the fensation thus produced is quite different from that which is felt from

an electric shock (L).

There is an experiment related by Dr Valli, which fecms to shew that nothing like an electric shock is felt, even when this influence is transmitted through a nerve fo as to excite convulfions. Having laid bare the nerves of a fowl's wing, without cutting them, and without killing the fowl, upon applying the metals very fmart movements were produced, but the animal remained perfectly tranquil. Nor was this owing to the

⁽K) There is an exception to this rule which ought to be taken notice of. M. Cotugno informs us, that when he was one day employed in diffecting a live mouse, he received a sensible shock from the animal. But as neither he nor any other person has ever been similarly affected in any other instance, it seems pretty certain that he was deceived into the belief of a shock from the sensation produced by the struggles of the animal he

⁽L) " No one (fays M. Humboldt) can speak more decidedly on this subject than myself, having made feveral experiments on my own person, the seat of which, in some instances, was the socket of a tooth which I had canfed to be extracted; in others, certain wounds which I made in my hand; and in others, the excoriations produced by four bliftering plafters." The following is the refult of these painful experiments. The galvanic irritation is always painful, and the more so in proportion as the irritated part is more injured and the time of irritation more prolonged. The first strokes are felt but slightly; the sive or six following are much more fensible, and even scarcely to be endured, until the irritated nerve becomes insensible from continued stimulus. The fensation does not at all resemble that which is caused by the electric commotion and the electric bath; it is a peculiar kind of pain, which is neither sharp, pungent, penetrating, nor by intermissions, like that which is caused by the electric fluid. We may distinguish a violent Broke, a regular pressure, accompanied by an unintermitting glow, which is incomparably more active when the wound is covered with a plate of filver and irritated by a rod of zinc, than when the plate of zinc is placed on the wound, and the filver pincers are used to establish the communication.

fowl being in a state of insensibility; for when the perves were pricked or irritated it screamed violently. But all animals shew signs of great uneasiness from an electric shock.

In general, it must be confessed, that animals under experiments of this kind feem reftlefs and uneafy. The great distinction of which we speak at present, confifts in this, that the electric fluid produces a shock and uneafy fenfation when any part of the body is introduced into the conducting chain; while the influence discovered by Galvani, on the contrary, when merely transmitted through the body in this manner, gives no shock, nor any sensation whatever, insomuch that we are not sensible of its passage. If this influence be made to act directly on a nerve, there is, no doubt, some kind of irritation produced, as appears from the effect of the metals upon the tongue, the eye, and other nervous parts: but still this action bears no analogy to that of the electric fluid. As the application of the metals to the organs of fense, produces in each organ the peculiar fensation for which it is constructed, as taste in the tongue, light in the eye, &c. so when nerves intended merely for muscular motion are subjected to the action of galvanism, the effect produced is motion in the muscles on which they are distributed.

If this view of the matter be just, it will explain why no shock is felt when the human body is made a part of the conducting chain. In that case the influence does not, in all probability, act directly upon any nerve; and we see that this influence possesses no power, like the electric fluid, of producing a convulfive shock, when merely passed through any part of the body; but it has this peculiar property, when passed directly through a nerve, it excites that nerve to perform the function for which it was intended by nature. To this it will no doubt be objected, that contractions may be excited in different parts of a frog without any division being made in its skin; and here it may be sup. posed that the influence is not made to pass directly through a nerve. But it ought to be recollected that the skin of these animals is abundantly supplied with nerves, whose trunks communicate at different places with those which supply the muscles; and that the contractions are always strong and easily excited, in proportion as they are applied near to the course of any of the nerves which go to the muscles. But though we had no doubt that the influence might be transmitted through the bodies of these animals, as well as through the human body, without any contractions being produced, we have thought it worth while to afcertain the fact by the following experiment.

A frog was prepared in the usual manner by coating its sciatic nerve with tinfoil, and laying the leg upon a plate of zinc. Another frog, in a very vigorous state, had its fore legs and chest attached to a rod of filver, and its posterior extremities to a rod of zine. The filver rod was applied to the tinfoil and nerve of the prepared frog, and the zinc rod to the plate of zinc upon which the leg was laid. Immediately very firong contractions took place in the leg; but no motion, nor the slightest mark of uneafiness, appeared in the other frog through the body of which the influence must have passed. It is necessary in this experiment to dry the body of the frog which is to ferve as

might be transmitted by the water upon its surface without paffing through its body.

There is an experiment mentioned by Dr Fowler. which shews a striking difference between electricity and galvanism. It was instituted with a view to afcertain the effects of the latter upon the blood-veffels. The Doctor relates it as follows: " Having laid bare, and separated from surrounding parts and from each other, the crural artery and nerve in the thigh of a full grown frog, I cut out the whole of the nerve between the pelvis and the knee: I then infinuated beneath the artery a thin plate of fealing wax, spread upon paper, and broad enough to keep a large portion of the artery completely apart from the rest of the thigh. The blood still continued to flow through the whole course of the artery in an undiminished stream. The artery, thus partially infulated, was touched with filver and zinc, which were then brought into contact with each other; but no contraction whatever was produced in any muscle of the limb. This experiment was frequently repeated upon feveral different frogs, both in whom the nerve was, and in whom it was not divided. The refult was uniformly the same. But vivid contractions were produced in the whole limb when an electric spark, or even a full stream of the aura was pasfed into the artery."

Before taking leave of this branch of our subject. it may be proper to take notice of one fact, which may be thought to militate against the doctrine we have endeavoured to establish. It is faid that a frog, exhausted and brought near to a charged electrophorus, has been found to refume its fusceptibility. We think this fact may be accounted for without admitting any connection between galvanism and electricity, merely by fupposing that the irritability of the muscles, which had been exhausted, was restored by the application of a moderate stimulus, (the electric stuid), of a kind different from those by which it had been exhausted. Such of our readers as are acquainted with the writings of modern physiologists on the subject of muscular irritability, will know that facts of this kind are very common. Thus it has been found by M. Humboldt, that the oxygenated muriatic acid has often restored irritability. To this explanation it will no doubt be objected, that the application of other stimuli, as alcohol and a folution of potash, instead of restoring, totally destroy the susceptibility of galvanism. Suspecting, that although these substances in a concentrated state destroy the susceptibility, yet that when sufficiently diluted, they might be found to have the opposite effect, we tried the following experiment, which confirmed our conjecture.

A frog, 57 hours after it had been decapitated, had ceased for above an hour to be capable of excitement by the application of the metals in any way that could be devifed. A few drops of alcohol being diluted with about a tea-spoonful of water, the nerve and the muscles which had been laid bare, as well as the whole skin of the animal, were wet with it. Upon the application of an excitatory arc, composed of four pieces, gold, zinc, filver, and tinfoil, a few very flight contractions of the toes were diffinctly observed. After this, no means that we could think of produced the fmallest excitement. Alcohol was now applied in a more cona conductor very carefully, otherwise the influence centrated state, but without any effect. The same

of the toes, had been used before the diluted alcohol was applied, but without effect. We have not tried

the application of potash much diluted.

The alva-

bal fo-

From what has been faid, we think we are fully warranted in faying, that although some of the phæno. mena discovered by Galvani bear a striking resemblance to some of those produced by the electric fluid; yet there are others, and these not the least important, which differ fo widely from any effects which have ever been feen to arife from that fluid, that they must derive their origin from some other cause. Our readers may probably think that we have dedicated too much time to this question; but as we conceive it to be the most important point which can be discussed on this subject, we thought it worth while to consider it at fome length; and we were the more convinced of the necessity of doing so, from this consideration, that there are still some writers of high authority who maintain the hypothesis, that galvanism and electricity are the

The next question that occurs to us with regard to the nature of galvanism is, whether or not it depends upon any law of animal life? To us it appears rather more probable, that the influence which incites the rei from muscles of animals to contract in the experiments of Galvani, is fomething quite foreign to the animals themfelves; as much fo as the electric fluid of the Leyden phial is to the animal which receives a shock from it, in both cases the body of the animal acting as a mere conductor. Upon this question, however, we confess that we have neither facts nor arguments to adduce fufficient to warrant our drawing any certain conclusion It will doubtless be asked, if this influence be something foreign to the bodies of animals, why do we never find it acting anywhere but in their bodies? why is it not, like the electric fluid, capable of being made evident to the fenses by its effects upon inanimate matter? The only answer which we are in a condition to give to this question is, that it may very possibly be capable of producing important effects upon inanimate matter, nay, these effects may be the subject of our daily observation; but for want of our being sufficiently acquainted with galvanism to point out the relation between these effects and their cause, the effects themselves are either not explained at all, or ascribed perhaps to some other power, with which they have no connection. In like manner, the electric fluid has doubtless been producing most important effects from the beginning of time; but, prior to the discovery of that fluid, these were either not explained at all, or confidered as originating from fome cause which, in fact, had no share in their production.

The great difficulty is to obtain some test by which we may detect the galvanic influence when actually prefent in inanimate matter. Hitherto we have no fuch test; nor should we know that such an influence exists, but for the effects which it produces upon the bodies of animals through the medium of their nerves. If we had any means of afcertaining its existence, either in a separate state, or conjoined with inanimate matter, the science would make a rapid progress, as it would be eafy to divertify experiments to as to discover its nature and effects. To detect it in a separate state is, in all probability, impossible; but that the zeal and inge-

four pieces of metal which produced the contractions nuity of philosophers will one day be able to discover some test of its presence in inanimate matter, there feems no reason to doubt.

We have made many experiments with a view to discover such a test, but hitherto without the smallest fuccess. In the trials we have already made, our views have been chiefly confined to the discovery of some chemical effects of this influence upon inanimate matter. M. Volta and other writers, having confidered the fenfation produced by it upon the tongue as fimilar to that occasioned by acids, we were not without hopes that it would be found to refemble that class of substances in fome of its other properties. We have therefore transmitted it through liquids tinged with the most delicate vegetable colours; but no change in thefe colours has been effected by the transmission of many galvanic shocks. We have also tried, in the same way, alkaline liquors, without any effect. We next dissolved in water different neutral salts, and other compound bodies, of which the parts are held together by the weakest affinities; but no change has been observed to be produced in them by the transmission of this influence. Our want of success, however, shall not deter us from continuing our efforts; we shall vary the nature of our experiments in every way that shall occur to us as likely to be attended with advantage; and if we should ultimately fail, we trust that others will be more fortunate. Every new fact which is discovered upon the subject tends to facilitate this investigation, by furnishing us with new guides to direct the course of our experiments. Dr Fowler is of opinion, that this influence, what Dr r weler

ever it may be, is not derived from the metals alone, this point, but that the animals at least contribute to its production, as well as indicate its prefence; and he feems to have been led to adopt this theory chiefly from two confiderations, neither of which appears to us to have much weight. They are the following: The necessity of a communication between the metals and the muscles, as well as between the metals and the nerves; and the observation, that animals have a more complete controul over its effects than one would expect them to have over an influence wholly external to them. But the communication between the metals and the muscles may be necessary to the contraction of the latter, tho' not to the production of galvanism; which, however, for want of any obvious effect, is not observed. That animals have some controll over the effects of galvanism upon themselves, may be very true; but this circumstance does not appear to us capable of proving any thing, as they have a controll over the effects of other stimuli in the same way. Thus, an animal of any refolution can bear, without betraying any uneafy fenfation, a blow which, inflicted unexpectedly, would have produced a convulfive start. The will does not in any degree controll the effects produced by galvanism upon our fenses of talle, seeing, &c.; that is, the sensations are produced, though we may have resolution not to betray them. But, says Dr Fowler, the will is not able to controll the effects of electricity, when the electricity is otherwise sufficiently strong to excite muscles to contraction. This argument may tend to shew, that galvanism differs from electricity; but as it must be admitted, that we can relift the contractions naturally produced by the application of other foreign stimuli, it by no means proves that animals have any power of 4 S 2 preventing

preventing the excitement or transmission of galvanism. Besides, though we cannot prevent an involuntary contraction of our muscles from taking place when an electric shock of considerable strength is passed through them, yet any man may with his hand draw sparks from the prime conductor of an electric machine without shrinking, though even these sparks would, if he were off his guard, produce a convulsive start.

We think without reason.

If the galvanic influence existed ready formed in the muscles or nerves of animals, the only thing requisite to the production of the contractions would be to make a communication between the nerves and muscles, by means of any fingle substance capable of conducting this influence; as water, for example: but the reverse is known to be true. It may be faid, however, that, although there is no proof that any influence naturally refides in the nerves or muscles capable of producing the effects mentioned by M. Galvani, these substances may still, by some power independent of the properties they possels in common with dead matter, contribute to the excitement of the influence, which is fo well known to exist in them after a certain application of metals. Upon this part of the subject, the observations of Dr Wells will be found to merit confiderable attention.

"It is known (fays that gentleman), that if a muscle and its nerve be covered with two pieces of the fame metal, no motion will take place upon connecting those pieces by means of one or more different metals. After making this experiment one day, I accidentally applied the metal I had used as the connector, and which I still held in one hand, to the coating of the muscle only, while with the other hand I touched the fimilar coating of the nerve, and was furprifed to find that the muscle was immediately thrown into contraction. Having produced motions in this way fufficiently often to place the fact beyond doubt, I next began to confider its relations to other facts formerly known. I very foon perceived, that the immediate exciting cause of these motions could not be derived from the action of the metals upon the muscle and nerve to which they were applied; otherwise it must have been admitted, that my body and a metal formed together a better conductor of the exciting influence than a metal alone; the contrary of which I had known, from many experiments, to be the case. The only fource, therefore, to which it could possibly be referred, was the action of the metals upon my own body. It then occurred to me, that a proper opportunity now offered itself of determining whether animals contribute to the production of this influence by means of any other property than their moisture. With this view, I employed various moist substances, in which there could be no suspicion of life to constitute, with one or more metals, different from that of the coatings of the muscle and nerve, a connecting medium between these coatings, and found that they produced the same effect as my body A single drop of water was even sufficient for this purpose; though, in general, the greater the quantity of the moisture which was used, the more readily and powerfully were contractions of the muscle excited. But if the mutual operation of metals and moisture be fully adequate to the excitement of an influence capable of occasioning muscles to contract, it follows, as an immediate confequence, that

animals act by their moissure alone in giving origin to the same influence in M. Galvani's experiments, unless we are to admit more causes of an effect than what are sufficient for its production." We do not quote the above reasoning as perfectly conclusive, for it by no means appears to us to be so; but it certainly gives some probability to the opinion, that galvanism is, as M. Volta supposes, the result of the action of two dry conductors, which touch each other immediately on one hand, while at their other extremities they touch conductors of what he calls the second class. (that is, moissure, for all the conductors of the second class contain water), and that the bodies of animals act merely as moisture.

One of M. Humboldt's experiments related above, appears to us to strengthen the conclusion, that the influence discovered by Galvani is something perfectly foreign to the bodies of animals. Can it be supposed that any substance which naturally resides in our bodies, should, in a few seconds after it is put in motion, convert the simple serous discharge of a blister into a dark coloured sluid, of a nature so acrid as to irritate and violently instance the skin wherever it touches it? We do not say that this is impossible, for we are too little acquainted with the laws of secretion to say with certainty what may, or what may not, produce such a change; but we know no similar alteration produced, in a few seconds, by a mere change of action in the vessels themselves.

We shall not undertake to determine the nature of The cause the cause which produces such astonishing effects. We which pro think it is certainly not the electric sluid, and probably duces the something which resides or is formed in the excitatory sects unarc, but we consider our knowledge of galvanism as known. It is infancy, and our stock of facts as infinitely too small to admit of our forming a just theory on the subject. Fortunately, however, the discovery of Galvani has attracted so much the attention of philosophers in every part of Europe, that new facts may be expected to come to light every day; and we hope the time is not very distant, when these may be so classed, as to entitle the subject to be ranked among the sciences.

While this article was in the press, we were favoured by a friend with an account of some German differtations on the subject, which we are obliged to insert in this irregular manner.

Mr Creve, surgeon in Wurtzburg, had an opportunity of observing the galvanic irritation on the leg of a boy, which had been amputated far above the knee in the hospital of that city. Immediately after the amputation, Mr Creve laid bare the crural nerve (kniekehlnerven), and surrounded it with a slip of tinsoil. He touched at once the tinsoil and the nerve with a French crownpiece. In that instant the most violent convulsions took place in the leg both above and below the knee. The remainder of the thighbone bent with force toward the calf; the foot was more bent than extended. All these motions were made with much force and rapidity. None were produced when the tinsoil was taken away, or when a steel pincer was used in place of a piece of silver, or when the tin or silver was covered with blood: but they were renew-

select. vol. 2.).

ed when these obstacles were removed. These phenomena continued till 38 minutes after the amputation,

when the limb became cold.

Dr Christopher Heinrich Pfaff (in Differtatione de Electricitate Animali, Stutgardt, 1793: fee also Gren's Journal der Physik, T. viii. p. 196, &c.) has classed the phenomena in a very orderly and perspicuous manner; and the result of the numerous experiments made by himself and others corresponds very nearly with our inferences in the preceding pages.

1. Phenomena of muscular contraction.

The general form of his experiments is the fame with that which we have placed at the beginning of this article; but the following varieties were observed:

The nerve being coated with tinfoil, it was always observed that the contractions were stronger when the filver first touched the muscle, and then the coating. If it touched the coating first, the effects were always, and very sensibly, weaker.

They were still stronger when the silver did not touch the muscle at all, but only the nerve and its

coating.

When the contractions were weaker at the begin-

ning, they also ceased sooner.

No contraction enfued from touching the coating only, or the nerve only, or the muscle only, with the filver.

Continuing the contact did not occasion any repetition of the contractions, except in some cases, where the filver was drawn along different parts of the coating, while its other end remained in contact with the nerve.

The contractions took place only in the muscles to

which the nerve led.

Their strength and duration were greater when the surfaces of contact were greater, and when the two metals touched each other in points or sharp edges.

A ligature, with a filk thread below the coating (that is, between the coating and the muscle, or part of the nerve touched by the silver), prevented all contraction; but not if the ligature was between the coating and the brain. If the nerve was cut through below the coating, and the parts separated a quarter of an inch, no contraction followed by touching the coating and the nerve or muscle: but it took place, if the parts were brought into contact; or even if a piece of any other nerve was put between the parts.

If a confiderable part of a bared nerve was infulated and coated, partly with tinfoil and partly with filver, contractions were produced in the muscle to which it led whenever the two metals were brought into con-

tact.

If one crural nerve be coated with tin, and the other with filver, contractions are produced in both legs

by bringing the metals into contact.

If the nerve be dry under the coating, or when the filver touches it, or in both places, we have no contractions; but they begin as foon as we moisten the nerve.

Dr Pfaff infers from these phenomena, that the nerve alone is subject to the irritation produced by the

two metals.

If the prepared frog be immerfed in water, fo that the coating touches the water, contractions are produced by touching the coating above water with the filver, while another part of the filver touches the

nerve, or the muscle, or even dips pretty deep in the water.

No fuch thing happens in oil; or, at best, the con-

tractions are very flight.

Dr Pfaff could not produce contractions without employing two metals, or a metal and charcoal.

A very thin covering of muscular slesh on the nerve did not altogether prevent the contractions, and in many cases did not sensibly diminish them.

If a piece of filver be laid on the muscles of the breast or belly, and be brought into contact with the

tin coating on the lumbal region, only the muscles of the breast or belly are affected, but not those of the

Dr Pfaff fays, that the involuntary muscles are not affected by galvanism; and refers for convincing proofs to a differtation by Dr Ludwig, shewing that the heart is not furnished with nerves, (Scriptor. neurolog. minor.

II. Irritation of the Organs of Sense.

Here Dr Pfaff's differtation contains nothing remarkable.

III. Conjectures as to the Caufe.

Dr Pfaff uses the same arguments that we have employed to refute the opinion of a similarity between the animal organs and the Leyden phial, and the opinion that electricity is the agent. He mentions the opinion of those who maintain that the agent is a fluid put into motion by means of its relation to the metals only, in their action on each other, and who consider the animal as merely serving as a conductor; and also serving, by its irritability, to give us the information of the presence of such a sluid, in the same manner as another kind of irritation, somewhat analogous to it, indicates the presence and agency of the electric sluid. It may therefore be called the Metallic Irritation; a term which will sufficiently diffinguish it.

But Dr Pfaff feems rather to think that the agent resides in the animal, and that the metals are the conductors (See a dissertation, entitled, Farther Contributions to the Knowledge of Animal Electricity, in Gren's Journal der Physik, T. viii. p. 377). This stuid he conceives to be intimately blended with the principle of life; nay, perhaps, to be the same. He mentions a thought of Professor Kielmayer, "that it may resemble the magnetic sluid in its manner of acting, giving connection to the distant particles of a nerve, as we observe a magnet give an instantaneous connection to each of a parcel of iron filings; all of which it would arrange in a certain precise manner, if they were sufficiently moveable, by giving momentary polarity to each." This somewhat resembles Newton's hypothetical whim read to the Royal Society, describing what may be done by

But all this is vague conjecture, and merits little attention. This will be better beftowed on an observation of M. Humboldt of Jena, "that a bit of fresh morelle (the Helvella mitra of Linnæus) may be substituted for a bit of nerve in the animal arc in these experiments." This is the only vegetable substance yet discovered to have this property. If the nerve be laid on the morelle, we have only to touch the morelle with the zinc, and the

means of an æther (See Birche's History of the Royal

muscular contractions immediately follow.

GARDECAUT,

Garden.

GARDECAUT, or GUARD DU CORD, in a watch, prevented. Hardly have they become tolerably well Carden, , is that which stops the fusee when wound up, and for acquainted with mankind, when the milk of human that end is driven up by the fpring. Some call it kindness is turned into gall and venom in their hearts. Guard-cock; others Guard du Gut.

GARDEN (Francis), better known to the public by the title of Lord Gardenstone, was born at Edinburgh June 24th, in the year 1721. His father was Alexander Garden of Troup; an opulent landholder in Aberdeenshire; his mother was Jane, daughter of Sir Francis Grant of Cullen, S.C.I.

After passing through the usual course of liberal education at the school and the university, he betook himself to the study of law for his profession. In the

Advocates, and called to the Scottish bar.

In his practice as an advocate he soon began to be distinguished, by a strong, native recitude of understanding; by that vivacity of apprehention and imagination, which is commonly denominated Genius; by fubtlety and fophistical artifice; by powers which, with diligence, might eafily attain to the highest eminence

f the profession. But the same strength, openness, and ardour of mind, which diftinguished him so advangive him a fondness for the gay enjoyments of convivial intercourse, which was unfavourable to his progress in juridical erndition. Shining in the focial and convivial circle, he became less solicitously ambitious than he might otherwise have been, of the character of an eloquent advocate, or of a profound and learned lawyer. The vivacity of his genius was averse from auftere and plodding fludy, while it was captivated by the fascinations of polite learning, and of the fine arts. Nor did he always escape those excesses in the pursuit of pleasure into which the temptations of opening life are apt, occasionally, to seduce the most liberal and ingenuous youth. But his cheerful conviviality, his wit, humour, tafle, good-nature, and benevolence of heart, rendered him the delight of all his acquaintance. He became his Majesty's Solicitor July 3d, 1764.

At length the worth of his character, and his abilities as a lawyer, recommended him to the office of a Judge in the Courts of Session and Justiciary, the fupreme judicatures, civil and criminal, for Scot-land. His place in the Court of Session he continued to occupy till his death; but had, fome years before, refigned the office of a Commissioner of Justiciary, and in recompence got a pension of 2001. per annum. Clear discernment, strong good sense, conscientious honefty, and amiable benevolence, remarkably diftinguish-

ed all his opinions and conduct as a judge.

We not unfrequently fee the gay young men of the prefent age, to turn, as they advance towards middle life, from the headlong pursuit of pleasure to a fordid and contracted felfishness, which excludes even those few good qualities that feemed to accompany their first thoughtless days. Their life is divided between fensuality and that anxious inhumane avarice and ambition whose ultimate object is, to provide gratifications to sensuality and pride. The kindling light of rectitude, and the first sparks of generous humanity, are extinguished in their breaks, as soon as those ebullitions of youthful passion and inexperience are over, by which the useful efficiency of their early good qualities was

It was far otherwife with Lord Gardenstone. As he advanced in years, humanity, taste, public spirit, became still more and more eminently the predominant principles in his mind. - He pitied the condition of the pealantry, depressed rather by their ignorance of the most skifful modes of labour, and by their remotenels from the sphere of improvement, than by any tyranny or extortion of their landlords. He admired, protected, and cultivated the polite arts. He was the ardent votary of political liberty, and friendly to every year 1744 he was admitted a member of the Faculty of thing that promifed a feafible amelioration of public e-

conomy, and the principles of government.

In the year 1762 he purchased the estate of Johnston, in the county of Kincardine. Within a few years after he began to attempt a plan of the most liberal improvement of the value of this estate, by an exmanly candour in argument, often more perfuafive than tention of the village of Laurencekirk, adjoining. He offered leafes of small farms, and of ground for building upon, which were to last for the term of one hundred years; and of which the conditions were extremely inviting to the labourers and tradefmen of the furroundtageously among the pleaders at the bar, tended to jug country. These offers were eagerly listened to. More desirous to make the attempt beneficial to the country than to derive profit from it to himself, he was induced, within a few years, to reduce his groundrents to one half of the original rate. - Weavers, joiners, shoe-makers, and other artisans in a considerable number, reforted to fettle in the rifing village. His Lordship's earnestness for the success of his project, and to promote the profperity of the good people whom he had received under his protection, led him to engage in feveral undertakings by the failure of which; he incurred considerable losses. Projects of a printfield, and of manufactures of linen and of stockings, attempted with fanguine hopes in the new village, and chiefly at his Lordship's risk and expence, misgave in fuch a manner as might well have finally difgusted a man of lefs fleady and ardent philanthropy with every fuch engagement. But the village still continued to advance. It grew up under his Lordship's eye, and was the favourite object of his care. In the year 1779, he procured it to be erected into a burgh of barony; having a magistracy, an annual fair, and a weekly market. He provided in it a good inn for the reception of travellers; and with an uncommon attention to the entertainment of the guests who might refort to it, furnished this inn with a library of books for their amusement. He invited an artist for drawing, from the continent, to fettle at Laurencekirk. He had the pleasure of feeing a considerable linen manufacture at length fixed in it. A bleachfield was also established as a natural counterpart to the linen-manufacture. Before his Lordship's death, he saw his plan of improving the condition of the labourers, by the formation of a new village at Laurencekirk, crowned with fuccess beyond his most fanguine hopes. He has acknowledged, with an amiable frankness, in a memoir concerning this village, "That he had tried, in some measure, a variety of the pleafures which mankind purfue; but never relished any fo much as the pleasure arising from the progress of his village."

In the year 1785, upon the death of his elder bro-

12 1. ther, Alexander Garden of Troup, M.P. for Aberdeenshire, Lord Gardenstone succeeded to the possession of the family estates, which were very considerable. Until this time his Lordship's income had never been more than adequate to the liberal expence into which his rank, and the generofity of his nature, unavoidably led him. But the addition of a fortune of about three thousand pounds a-year to his former revenue, gave him the power of performing many acts of beneficence with which he could not before gratify his good heart. It was happy, likewife, that his fuccesfion to this ample income, at a period when the vigour of his constitution was rapidly yielding to the infirmities of old age, enabled him to feek relief, by a partial ceffation from bufiness, by travel, and by other means, which could not have been eafily compatible with the previous state of his fortune.

In the month of Sept. 1786, he fet out from London for Dover, and passed over into France. After visiting Paris, he proceeded to Provence, and spent the winter months in the genial climate of Hieres. In the fpring of 1787 he returned northwards, vifiting Geneva, Switzerland, the Netherlands, and the Dutch provinces, and passing through Germany into Italy. With a fond curiofity, attentive alike to the wonders of nature, to the noble monuments of the arts, and to the awful remains of ancient grandeur, with which Italy abounds, he visited all its great cities, and surveyed almost every remarkable and famous scene that it exhibits.

His first object, in these travels, was to obtain the restoration of his declining health by the influence of a milder climate, by gentle, continued, and varied exercife; by that pleasing exhibitantion of the temper and spirits, which is the best medicine to health, and is most successfully produced by frequent change of place, and of the objects of attention. But the curicfities of nature and art, in those countries through which he travelled, could not fail to attract, in a powerful manner, the curiofity of a mind cultivated and ingenious as his. He, whose breast glowed with the most ardent philanthropy, could not view the varied works and manners of a divertity of nations of his fellow men, without being deeply interested by all those circumstances which might appear to mark their fortunes as happy or wretched. He eagerly collected specimens of the spars, the shells, the strata, of rocks, and the veins of metals, in the several countries through which he passed. He amassed also cameos, medals, and paintings. He enquired into science, literature, and local institutions. He wrote down his observations, from time to time; not indeed with the minute care of a pedant, or the oftentatious labour of a man travelling with a defign to publish an account of his travels; but simply to aid memory and imagination in the future remembrance of objects useful or agreeable.

After an absence of about three years, he returned to his native country. The last years were spent in the discharge of the duties of his office as a judge; in focial intercourse with his friends, among whom was the venerable Lord Monboddo, and others of the most respectable characters that our country has to boast of; in the performance of a thousand generous offices of benevolence and humanity; in cherishing those fine arts, of which he was an eminent admirer and judge; and above all, in promoting the comfort, and encou-

raging the industry of his dependants, and in lending Garden. his aid to every rational attempt at the improvement of public economy and public virtue.

St Bernard's Well, in the neighbourhood of Edinburgh, had been, long since, distinguished for the medicinal virtues of its waters. But various circumstances had also concurred of late to throw it into neglect. Yet its waters being strongly mineralized by a sulphurated hydrogenous gas, were, by this means, unqueftionably qualified to operate, with highly beneficial effects, in the cure of various diseases. The qualities of this mineral water falling under Lord Gardenstone's notice, he was induced to purchase the property of the well, to direct it to be cleared from furrounding obstacles, which contaminated the virtues of the water, or made it inaccessible; to erect a beautiful and commodious edifice over it; and to appoint proper persons to distribute the water, for a very trivial compensation, to the public. The well lies at a distance from Edinburgh, which is very convenient for a summer morning's walk. Within the few years which have passed fince Lord Gardenstone's benevolent care brought it into notice, it has attracted many of the inhabitants of that city to visit in the mornings of spring and summer. And, undoubtedly, the agreeable exercise to which they have thus been allured, and the falutary effects of the water, have contributed, in no mean degree, to dispel disease, and to confirm, or re-establish health. Such monuments are worthy to preferve the memory of a patriotic and a good man!

As an amusement for the last two or three years of his life, when his increasing infirmities preclued him from more active exercise, and from mingling so frequently in the fociety of his friends as was agreeable to his focial and convivial temper, he bethought himfelf of revifing some of the jeun d'esprit, and light fugitive pieces, in which he had indulged the gaiety of his fancy, in his earlier days; and a small volume of poems was published, in which the best pieces are, upon good authority, ascribed to Lord Gardenstone. He revised also the memorandums which he had made upon his travels, and permitted them to be fent to prefs. The . two former volumes were published one after another while his Lordship was yet alive; the third after his death. They met with a very favourable reception in the world, and were honoured with the high approbation of the most respectable writers of periodical criticifm. They convey much agreeable information, and bespeak an elegant, enlightened, and amiable mind. The last volume is flled chiefly with memorandums of his Lordship's travels in Italy; and contains many interesting criticisms upon some of the noblest productions of the fine arts of painting and sculpture.

His Lordship's health had long been declining; and he died a bachelor on the 22d of July 1793, lamented by his relations and friends, by his tenants and humble dependants, and by all true patriots and good men to

whom his merits and virtues were known.

Such is the account of Lord Gardenstone's life, which was prefixed to the third volume of his travelling memorandums; and though it was no doubt an effusion of fond friendship, we believe that the praise which it bestows on his Lordship is not much exagge. rated. In the latter years of his life, it must indeed be confessed, that he contracted intimacies with men unGas || Geocentric

worthy of his regard; and that his attachment to liberty made him form expectations from the French revolution, which even the events which he saw ought to have repressed. But his mind was by that time weakened by disease; and it would be very unjust to balance the imprudencies of one or two years against the meritorious actions of a whole life. Besides his travelling memorandums and his poems, his Lordship published a Letter to the Inhabitants of Laurencekirk, the most valuable, in our opinion, of all his publications; for it contains perhaps the most falutary advices which were ever offered to the inhabitants of a manufacturing town, for the regulation of their conduct towards each other. That the people of Laurencekirk have followed these advices, it would give us pleasure to learn on good authority.

pleasure to learn on good authority.

GAS. See that article, Encycl. and CHEMISTRY-Index in this Supplement. We have introduced the word here, to notice fome experiments made by Professor Jacquin of Vienna, at the defire of Dr Chladni, on the different gases as the vehicle of sounds. A glass bell was furnished with a metallic stopper cemented to a neck at the top; and in the bore of this cock, within the glass, a small flute or pewter (etain) about six inches in length was fixed. The glass being then placed on the shelf of the pneumatic vessel, and filled with any particular kind of gas, a bladder also filled with the same gas, and provided with a cock, was adapted to the external aperture of the coek belonging to the bellglass. In this disposition of the apparatus, the flute was made to found by gently preffing the bladder. Com parative experiments were made with atmospheric air, oxygen, hydrogen, carbonic acid, and nitrous gas. The intensity of the found did not vary; but when compared with that produced by atmospheric air, the oxygen gas gave a found half a tone lower; azotic gas, prepared by different methods, constantly gave a found half a tone lower; hydrogen gas gave nine or eleven tones higher; carbonic acid gas gave one-third lower, and nitrous gas also very nearly a third lower. A mixture of oxygen gas and azote, in the proportions of the atmospheric air, afforded the tone of this last; that is to fay, it was half a tone higher than each of the component parts alone. When the two gafes were not uniformly mixed, the found was abominably harsh. Chladni intends to give a fuller account of these interesting experiments. Journal de Physique, Vol. IV. N. S. p. 57.

GAZONS, in fortification, turfs, or pieces of fresh earth covered with grass, cut in form of a wedge, about a foot long, and half a foot thick, to line or face the outside of works made of earth, to keep them up, and

prevent their mouldering.

GEOCENTRIC PLACE of a planet, is the place where it appears to us from the earth; or it is a point in the ecliptic, to which a planet, feen from the earth, is referred.

GEOCENTRIC Latitude of a planet, is its latitude as feen from the earth, or the inclination of a line connecting the planet and the earth to the plane of the earth's (or true) ecliptic: Or it is the angle which the faid line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic.

GEOCENTRIC Longitude of a planet, is the distance measured on the ecliptic, in the order of the figns,

between the geocentric place and the first point of Geometrics.

GEOMETRICAL METHOD OF THE ANCIENTS. Georgia The ancients established the higher parts of their geometry on the same principles as the elements of that science, by demonstrations of the same kind: and they were careful not to suppose any thing done, till by a previous problem they had shewn that it could be done by actually performing it. Much less did they suppose any thing to be done that cannot be conceived; such as a line or series to be actually continued to infinity, or a magnitude diminished till it become infinitely less than what it is. The elements into which they resolved magnitudes were sinite, and such as might be conceived to be real. Unbounded liberties have of late been introduced; by which geometry, which ought to be perfectly clear, is filled with mysteries.

GEOMETRICAL Solution of a problem, is when the problem is directly refolved according to the strict rules and principles of geometry, and by lines that are truly geometrical. This expression is used in contradistinction to an arithmetical, or a mechanical, or instrumental solution, the problem being resolved only by a ruler

and compasses.

The fame term is likewife used in opposition to all indirect and inadequate kinds of solutions, as by approximation, infinite series, &c. So we have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals, though there are mechanical ways, and others, by in-

finite series, &c.

GEORGIUM Sidus (fee Astronomy-Index, Enevel.) has no fewer than fix fatellites revolving round it, all discovered by Dr Herschel. Of the two which he first discovered, one was found to revolve in 8 days 17 h. 1 m. 17 fec. at the distance of 33" from its primary; and the other in 13 d. 11 h. 5 m. 1,5 fec. at the distance of 44",23. The planes of their orbits form fuch large angles with that of the planet itself, and consequently of the ecliptic, as to be almost perpendicular to it. To this remarkable departure from the analogy of the old planets, another still more fingular has been lately announced. They move in a retrograde direction! The new fatellites revolve as follows, the periodical times being inferred from their greatest elongations: The interior fatellite in 5 d. 21 h 25 m. at the distance of 25",5. A satellite intermediate between the two old ones in 10 d. 23 h. 4 m. at the distance of 38',57. The nearest exterior fatallite at about double the distance of the farthest old one, and consequently its periodical time 38 d. 1 h. 49 m. And the most diftant fatellite full four times as far from its primary as the old fecond fatellite. Whence it will take at least 107 d. 16 h. 40 m. to complete its revolution. Whether the motions of these four be direct or retrograde, is, we suppose, not yet determined.

From fome observations of the Doctor, with an excellent seven-feet telescope, certain appearances, resembling that of two rings surrounding the planet, and crossing each other at right angles, were seen on several different days. They were not altered in position by turning the speculum in its cell; but (says Mr Nicholson) there is little doubt that they were optical deceptions, because they kept their position with respect to the tube, after the relative position of the parallel had

cause they did not appear with larger telescopes applied during the course of ten years. The disk of the Georgium Sidus is flattened. It therefore revolves with considerable rapidity on its axis. From the very faint light of the satellites, they are observed to disappear in those parts of their orbits which bring them apparently nearest the planet. This does not arise from an atmosphere; for the effect is the same, whether the satellite be within or beyond the planet.

GÉRARD (Alexander, D. D.) was the eldest son of the reverend Gilbert Gerard minister of Chapel-Garioch, in the county of Aberdeen. He was born on the 22d of February 1728, and received the first rudiments of his education at the parish school of Foveran

in the fame county.

It may perhaps be proper to inform our English readers, that in every parish in Scotland there is a school where, for very small sees, the youth of the parish are not only taught to read the English language, to write, and to perform the elementary operations of arithmetic, but are also instructed in the Greek and Latin languages. Of these schools, many of the masters were, about fixty years ago, eminent for classical learning; and it seems that Mr Forbes, the master of the school of Foveran, possessed fuch fame as a teacher, that Mr Gerard judged it more expedient to commit his son to his care than to have him educated at the school of his own parish, and under his own immediate inspection. The attainments which that son afterwards made in literature, evince that his judgment was correct, and that the school-master of Foveran deserved the same which he enjoyed.

Young Gerard, however, did not remain long at Foveran. His father died when he was but ten years old; and his mother removing foon afterwards with her family to Aberdeen, he was of course put to the grammar-school in that city: but so solid was the foundation which had been already laid, that in two years time he was deemed sit for the university, and was accordingly entered a student in Marischal college. Such rapid progress supplies the place of that testimony which we have not been able to procure, respecting his

early attachment to literature.

After completing the usual academical course of sour years in the study of Greek, Latin, mathematics, and philosophy, he was admitted to the degree of master of arts; and immediately afterwards commenced the study of theology, which he prosecuted in the universities of Aberdeen and Edinburgh. In 1748, when he had little more than completed his twentieth year, he was licenced to preach in the church of Scotland, and two years afterwards was chosen assistant to Mr David Fordyce prosessor of philosophy in the Marischal college and university of Aberdeen. In this capacity he performed the duties of the absent professor till the 7th of July 1752, when he was appointed successor to Mr Fordyce, who had been drowned on the coast of Holland, as has been already related in the Encyclopædia.

At that period it was the practice in the Marischal college, as it continued to be in the King's, for the same professor to carry forward a class of students for three successive years through all the different branches of philosophy which were taught in the college. These were, Logic, Ontology, Pneumatics, Morals, Politics, and Natural Philosophy; and Mr Ge-

SUPPL. VOL. I. Part II.

MATHEMATICS and the GREEK language were taught

by separate professors.

About the year 1754, a very material alteration was made in the order of teaching philosophy in the university of Aberdeen; and in the Marischal college each professor was restricted to one department of science. The principal and professors in that college, justly observing that the public is interested in every thing which relates to education, thought it incumbent upon them to lay before that public the reasons which had determined them to deviate from the arrangement which they had hitherto observed; and they employed professor Gerard to draw up these reasons. This task he performed in a small pamphlet, which, being printed by the appointment of the college, appears to have given

very general satisfaction.

This, indeed, it could hardly fail to do; for the judicious author points out very clearly the inconveniences of the old, and the advantages of the new plan of academical study. Having observed, that the philosophy which had fo long kept possession of the schools, confifted, in a great measure, of verbal subtleties and theories ill-grounded, though ingeniously devised, he proceeds to contrast it with the philosophy of Bacon and Locke, and to show of how little value the former is when compared with the latter. He then enters on a brief examination of the scholastic logic, and proves, to the conviction of every impartial judge, that the art of fyllogizing, though a proper enough introduction to a philosophy which was built on general principles, either taken for granted, or founded on very narrow and inadequate observation, is by no means fitted to affift the mind in the cultivation of that science which is deduced by induction from particular facts. "The only basis of philosophy (says he) is now acknowledged to be an accurate and extensive history of nature, exhibiting an exact view of the various phenomena, for which philosophy is to account, and on which it is to found its reasonings. This being the reformed state of philosophy, great inconveniences must be found in profecuting the scholastic order of the sciences. The fludent must make a transition at once from words and languages to philosophy, without being previously introduced to the knowledge of facts, the fole foundation of, and preparation for it; he must be hurried at the first into the most abstrufe, difficult, and subtle parts of it; he must be put upon examining the nature, foundation, and different kinds of evidence and reasoning, before he is acquainted with any specimens of these kinds by which they may be illustrated. And in proportion as philosophy is more improved, and more thoroughly reformed, these inconveniences must become more sen-

"The view of these (continues he) induced the mafters of the Marischal college to think of altering the hitherto received order; and after the most mature deliberation, made them at last resolve, that their students should, after being instructed in languages and classical learning, be made acquainted with the elements of history, natural and civil, of geography and chronology, accompanied with the elements of mathematics; that they should then proceed to natural philophy; and, last of all, to morals, politics logic, and metaphysics."

In vindicating this arrangement, he labours with

great earnestness, and we think with complete success, to shew the propriety of making logic the last branch of academical study. "All sciences (says he), all departments of knowledge whatever, must be premised as a ground work to gehuine logic. History has one kind of evidence, mathematics another, natural philosophy one still different the philosophy of human nature another distinct from all these; the subordinate branches of these several parts have still minuter peculiarities in the evidence appropriated to them. An unprejudiced mind will in each of these be convinced by that species of argument which is peculiar to it, though it does not reflect how it comes to be convinced. By being conversant in them, one is prepared for the study of logic; for they supply him with a fund of materials; in them the different kinds of evidence and argument are exemplified; from them only those illustrations can be taken, without which its rules and precepts must be un-

"All just conclusions concerning the works of nature must be founded on an induction of particulars. And as in natural philosophy these particulars are supplied by observations and experiments on natural bodies; to in logic, the particulars, of which an induction must be made, are to be learned only from the body of arts and sciences. These are the subjects on which observations must be made, in order to lay down rules for investigating and proving the truths of which they are made up; just as the genuine performances of any art are what must be considered and observed in laying down the rules of that art. No folid precept can be formed in logic, except by examining arts and sciences, and attending to the method of reasoning used in them, and to the evidence that accompanies it. In proportion as they are cultivated, and no farther, logic may be improved. And what is true of the invention of logic, is true likewise of the study of it. It can be understood no farther, than the several sciences which it reviews and criticifes are previously understood. Accordingly we find, that all the fystems of logic which have not been compiled from a careful review and examination of the feveral sciences, consist more of ingenious fubtleties than of ufeful precepts affilling to the mind in the various parts of knowledge. And when logic has been learned before the other sciences, the fubiliantial parts of it have been scarce attended to, or made any use of, in the profecution of them; nor fo much as understood, but in as far as the mind was gradually opened, and brought to recollect them in its progrefs through the fciences.

"Logic is precifely the same to philosophy that works of criticism are to poetry. The rules of criticifm are formed by an accurate scrutiny and examination of the belt works of poetry. To one who had never read a poem, these rules would be obscure and useless; he could not comprehend them, far less would he be able to form a judgment of their justness, and of the reasons on which they are founded. If one peruses the best poetical performances, he will acquire some degree of taste, though he has never professedly studied the rules of criticism; and he will, at the same time, lay in materials, and obtain a stock of examples, which may render these rules intelligible to him, and enable him to judge whether they are just or not. And by afterwards fludying thefe rules, he improves, refines, things, though often transiently and inattentively; they

and corrects his tafte, perceives the principles on which Gerry he has founded all his judgments, though he did not in the mean time think of them, and gains additional fecurity against his judging wrong. This may illustrate what has been faid of the place which logic ought to hold among the sciences. The observations made in it, both concerning the methods of invention and of probation, are founded on, and deduced from, the feveral sciences in which these methods are used. Neither the observations themselves, nor the reasons on which they are built, can be fully comprehended by one abfolutely ignorant of these sciences. In studying the particular fciences, reason will spontaneously exert itself: if the proper and natural method of reasoning is used, the mind will, by the native force of its faculties, perceive the evidence, and be convinced by it, though it does not reflect how this comes to pass, nor explicitly confider according to what general rules the understanding in exerted. By afterwards ftudying these rules, one will be farther fitted for profecuting the feveral sciences; the knowledge of the grounds and laws of evidence will give him the security of reflection, against employing wrong methods of proof and improper kinds of evidence, additional to that of instinct and natural genius. And thus logic will greatly contribute to improvement in knowledge; and more so, when it is used as a review of the method taken in the profecution of science, of the foundations gone upon, and of the general rules that have been observed, than when it is applied as an introduction to the elements of science; for in the former case, its rules can be perfectly understood, sufficiently illustrated, and put in practice as they are learned, which in the latter is quite impossible."

Having thus vindicated the new arrangement with respect to the place which it assigns to the study of logic, he proceeds to inquire in what order the other sciences should succeed each other. "Ethics (says he) or moral philosophy is founded as well as logic on pneumatics, and must therefore come after it. The constitution of man, and his feveral active powers, must be explained, before his bufiness, his duty, and his happiness, can be discovered. Jurisprudence and politics, taking a more complex view of man than morals, by confidering his various states, as well as his nature and powers, cannot, with any propriety, be introduced till morals have

first been studied.

"It only remains then to determine whether natural philosophy or pneumatology ought, in the order of teaching, to have the preference. And many confiderations feem to require that the former should be studied first. If it were not, pneumatology would be too far disjoined from the practical fciences founded on it; one of which, logic, ought, as we have feen, to be taught last of all. Besides, we ought always to begin with the easiest and most obvious subjects, and to proceed gradually to the most difficult; and in order to this, we ought to comply as much as possible with the natural openings and progress of the human mind. Now it is evident, that the mind receives first of all impressions and ideas of those fensible things with which it is furrounded. It is not till after it has exercised its faculties about them that it reflects on its own operations, or acquires perceptions of them. We are from, our earliest infancy accustomed to observe external

lie always in our view, they force themselves upon us, and we cannot avoid regarding them more or less. But we seldom attend to the operations of our minds in our earlier years; it is late before we acquire distinct notions of them, or can eafily and readily make them the objects of our contemplation. Farther, external fensation, by which bodies are perceived, is a more palpable kind of evidence than internal, from which all our knowledge of spirits is derived; it strikes and affects us more. The philosophy of spirits, as well as that of bodies, is founded folely on experiments and observations; but in the latter it is much easier to make these than in the former: we can put bodies in any fituation that we please, and observe at leisure their effects on one another: but the phenomena of the mind are of a less constant nature; we must catch them in an instant, and be content to glean them up, by observing their effects as they accidentally discover themselves in the several circumstances of life. The reasonings also by which conclusions are deduced concerning mind are of a more abstrufe and difficult nature than those employed in the science of bodies; the ideas about which they are conversant arc apter to be confounded with one another, and are with greater difficulty kept distinct. On all these accounts, natural philosophy must be to young minds easier than pncumatology, and confequently should be tanght first."

For this long digression, if such it shall be deemed, we are perfuaded that those who retain any attachment to the place where their minds were first imbued with the principles of fcience, will think no apology requisite, when they are informed, that the plan of education, which is here so ably defended, was about the fame period adopted by both colleges in the univerfity of Aberdeen; that the writer of this article had his own education in the King's college; and that in the prosperity of that college he still feels himself deeply interested. Let it be remembered, too, that the publication from which this extract has been made, furnishes a proof of professor Gerard's abilities, and of the estimation in which he was held by his colleagues at a very early period of life; and then furely the digreffron will not be thought impertinent

He was now professor of moral philosophy and logic, and of these sciences alone: but though his plan of education in the Marifchal College shews the order in which his lectures were arranged, we have not been able to lezrn on what foundation he built his fystem of ethics. As Hutcheson's Moral Philosophy was then much read and admired, it will not detract from Mr Gerard's merits to fuppose, that, with his predecessor Mr Fordyce, he was an advocate for the moral sense of that author; for there are but three or four foundations on which a fyftem of ethics can be raifed; and it may be doubted whether there be one of them which is not as old as the age of Plato. It would indeed be ridiculous in any modern (A) to aim at giving a new

foundation to moral virtue; for virtue must have been Gerard. practifed upon some steady principle from the earliest period of human fociety; and the most eminent profesfor will find fufficient room for the display of all his learning and ingenuity in illustrating the principle which his own judgment has led him to adopt.

Of this professor Gerard was fully sensible; and whilft he was confcientiously discharging his duty to his pupils, he neglected no opportunity of improving himself. He was member of a literary society at Aberdeen, of which the respectability will not be questioned, when it is known that it consisted of such men as the late Doctors Blackwel, Gregory, Reid, and Campbell, with Dr Beattie, and many others of perhaps equal talents, though not known to the world as authors (B). This fociety met regularly during the winter, we believe once every fortnight; the members communicated their fentiments with the utmost freedom; every novel opinion was fure to be canvaffed on all fides with impartiality; the understandings of the members were thus mutually whetted; and hence originated Reid's Inquiry into the Human Mind, Gregory's Comparative View, Gerard's Esfay on Genius, Beattie's Effay on Truth, and Campbell's Philosophy of Rhe-

On the 5th of September 1759 Mr Gerard was ordained a minister of the Church of Scotland: on the 11th of June 1760, he was appointed prefessor of divinity in the Marifchal college, and minister of the Grayfriars church in Aberdeen; and at the same time, as we suppose, created doctor in divinity.

On the 18th of June 1771 he refigned his professorship in Marischal College, together with his churchliving, and was preferred to the theological chair in the university of King's College, then become vacant by the death of professor Lumisden. In that station he continued, profecuting his studies, beloved by his colleagues, and revered by his pupils, till his birth-day 1795; when, having just completed his 67th year, lie died without a groan. His death was occasioned by a fchirrous tumor, which began to appear on his face in the year 1794, but without confining him to the house, or, except for a very few weeks, interrupting his usual pursuits. It impaired, however, his health, and gradually undermined his constitution. Of this he was very soon sensible; but he saw his dissolution approaching with the utmost composure and refignation, and preserved to all about him so much of that equanimity and placidness of temper which had marked the whole course of his life, that of him may truly be said,

> Multis illi multos annos precantibus Diri carcinomatis veneno contabuit, Nexibufque vitæ paulatim refolutis, E terris, meliora sperans, emigravit.

Were we to hazard an opinion of Dr Gerard's intellectual powers, from having attentively perufed his 4 T 2 works,

⁽A) The friends of Mr Godwin, who affect to call his political justice the new philosophy, will, of course, think this a rash affertion; but were it worth while, it would be no very difficult task to produce, from the atheistical writers of antient Greece, fomething similar even to his wildest paradoxes. Dr Gerard was too well acquainted with the subject, and too warm a friend to genuine virtue, to pretend to novelty in moral

⁽B) Such as Professor Thomas Gordon, who read lectures in the King's College for 63 or 64 years, and whose learning was equalled only by his virtues.

Gerard. works, we would fay that he possessed great rectitude of judgment, rather than any remarkable vigour of ing master of almost any subject, though perhaps he had not the imagination requifite for making discoveries in science; and that his attainments were solid rather than brilliant. What he knew, he knew thoroughly; but to us his knowledge feems to have been the reward of labour.

* Dr Beat-

By one, to whom he was well known, and who himself stands high in the republic of letters *, we are affured that he had improved his memory to fuch a degree, that, in little more than an hour, he could get by heart any fermon of ordinary length; though far from availing himself of this talent, as many would have done, he composed with care all the fermons that he preached. In early life he made it a rule not to study after supper; and from that rule he never deviated, but amused himself after that time, either with the conversation of his family, or with any light reading that came in his way; and he was generally in bed by half past eleven. He seems not to have approved of early more than of late study; for though, for a few years, when as professor of philosophy he had various sciences to teach, he rose regularly, during winter, at five in the morning, he discontinued that practice as soon as he had it in his power, and did not enter upon ferious fludy till after breakfast, generally about 10 o'clock. He was indeed very laborious through the day, and could with difficulty be perfuaded to take any bodily exercife; but being remarkably temperate in eating and drinking, he enjoyed very good health, which was only occasionally interrupted by those stomach complaints, to which men of fedentary lives are often subject.

The fruits of this incessant study were, besides the lectures which he read to his different classes, 1st, An Essay on Tasse, to which, in 1756, was adjudged the gold medal by the Philosophical Society of Edinburgh (See Societies, Encycl.), which had proposed Taste as the subject for a prize. Of this essay there has been a fecond, and a third edition; of which the last, which was published in 1780, is considerably enlarged and improved. 2d, Differtations on the Genius and Evidences of Christianity, published in 1766. 3d, An Essay on Genius, published in 1774. 4th, Two volumes of Sermons; of which the first was published in 1780, and the second in 1782. 5th, A part of his theological course, entitled The Pastoral Care, which was published in 1799 by his fon Dr Gilbert Gerard, who fucceeded him as professor of divinity in the King's college and univerfity of Aberdeen. Besides these works Dr Gerard published many single fermons, which were

preached on occasional subjects.

Of this amiable and respectable instructor of youth, we have been favoured with the following character, drawn by a man of talents and virtue +, who was first + The Rev. his pupil and afterwards his friend; and though it vie, Old Amade part of a funeral fermon, we believe that, by those who were most intimately acquainted with Dr Gerard, the panegyric which it contains will not be

deemed extravagant.

"In domestic life, his conduct was amiable and exemplary. He possessed, in a high degree, that kindness of heart and affability of manner which interested him and esteem of his colleagues. Possessing more than or-

at all times in the happiness of his dependants, preser. Geran ved good humour in his house, and endeared him to his mind; that he was capable, by intense study, of becom- family. He knew how to check improprieties without harshness, and when and how to indulge without impairing his authority. His natural good fenfe, fleadiness, and prudence, prevented him from being thrown into confusion by the adverse incidents of life; and enabled him, in prefling emergencies, to adopt wife measures, and to administer salutary counsel. His tender fympathy foothed the troubled hour of forrow; his rational and friendly advice guided his family thro' the perplexities of life, and he feelingly rejoiced in all their innocent enjoyments. His attachments were not confined to his family or his relatives; he was susceptible of warm friendship. In selecting the objects of it he was cautious, always preserring those whose merits entitled them to confidence and regard. His attachment, flowly formed, was not to be shaken by every oblique infinuation, or by every idle report to the prejudice of his friend. Steady in his professions of regard, he was capable of confiderable and difinterested exertions to ferve those whom he really esteemed. To his judicious advice they had ready access; and his best efforts to promote their good they could always command. As a member of fociety, his house was ever the feat of hospitality, and his door was always open to the stranger. In entertaining his friends, he equally avoided the extravagance and oftentation which did not become his character or fuit his fortune, and the rigid economy which marks the conduct of those who give with a reluctant and a sparing hand. He neither anxiously courted, nor affectedly shunned learned conversation. While he never obtruded upon company fubjects which, by the display of superior knowledge or abilities, were calculated to gratify his own vanity at the expence of hurting others, he always studied, as far as propriety would admit, to adapt his conversation to the temper and inclinations of his affociates. To please the young, and to promote their harmless festivity, was ever his delight; with cheerfulness he descended to their trivial amusements, and in his prefence they felt no restraints but those which virtue and decency impose. Though he often left for a little studies in which he was keenly engaged, to enjoy the conversation of a friend, he never suffered his love of fociety, one of his strongest passions, to induce him to facrifice any important literary purfuit, or to neglect any necessary business.

"As a clergyman, the office which he held for feveral years in Marischal college rendered it his duty to be a daily preacher, and gave him a feat in the ecclefiastical courts. But the unavoidable labour of preparing prelections for his theological pupils, did not prevent his unremitting attention to his public exhibitions in the pulpit. These were marked by that distinctness of arrangement, that justness of reasoning, and that accuracy of composition, which effectually secured the approbation of the ablest judges; while by their plainness and simplicity, they failed not of promoting the edification of the meanest capacities. To the low arts of acquiring popularity he never stooped: But his prudence, his good fense, his exemplary conduct, and his ministerial diligence, established his respectability and usefulness, and procured him the full confidence

ard dinary excellence, envy never led him to depreciate the merits of other preachers. Though one of the best of judges, he was always one of the most candid hearers. When by his translation to the university of King's college he was releafed from the labour of constant preaching, far from shewing any aversion to discharge the most public ministerial duties, he was always obedient to presbyterial appointments; and while health and strength remained, willing to oblige his clerical friends by appearing in their pulpits. Nor in private life did he ever lose fight of the character of a clergyman. Having in a publication ably defended its respectability, in opposition to the scoffs and sneers and fophisms of modern fceptics; he considered it as his honour, in his life and conversation, to display its dignity and importance; and to shew that the gravity of a Christian pastor is perfectly confistent with the good breeding of a gentleman, and with the cheerfulness, af fability, and ease of an agreeable companion.

"As a man of letters, his attainments were far above those at which the generality of students arrive. In his literary pursuits, he had all the advantages of a judgment uncommonly clear and diffinct; aided, from his earliest years, by the most indefatigable and persevering study. 'The well earned reputation with which, before he was promoted to the theological chair, he taught in Marischal college different sciences, inconteffibly proves that his powers, not confined to one subject, justly entitled him to eminence in feveral branches of literature. His publications, feveral of which have been translated into other languages, promise fair to extend his fame, and to liand it down to generations yet unborn; and his unremitting labours promifed still a farther contribution to the general stock of learning.

"As a professor of divinity, he will be long and gratefully remembered by his numerous pupils. This was his peculiar department, and in this he shone. Posseffing large stores of theological knowledge, he was judicious in felecting his fubjects, happy and fuccessful in his manner of communicating instruction. He had the merit of introducing a new, and in many respects a better plan of theological education, than those on which it had been formerly conducted. Liberal, but not loose, in his sentiments, his great aim was, not to impose by his authority upon his pupils any favourite fyftem of opinions; but to impress them with a sense of the importance of the ministerial office, to teach them the proper manner of discharging all its duties, and to enable them, by the knowledge of Scripture, to form a just and impartial judgment on controverted subjects. Solicitous for their improvement, he was ever ready to encourage rifing merit by his warmest approbation; and reluctant to damp even unfuccessful efforts of genius by deferved cenfure. Having a constant eye to what is practically ufeful, rather than to unedifying specula-

tion, he enjoined no duty which he was unwilling to Germinaexemplify in his own conduct. Hence that frict regard to the ministerial character which he uniformly displayed, and hence his uncommon punctuality in attending the public ordinances of religion."

GERMINATION, among botanists, is a very interesting subject, on which the late discoveries in chemistry have thrown much light fince the article GER-MINATION was published in the Encyclopædia. In the year 1793, Mr Humboldt discovered, that simple metallic substances are unfavourable to the germination of plants, and that metallic oxyds favour it in proportion to their degree of oxydation. This discovery induced him to fearch for a substance with which oxygen might be fo weakly combined as to be eafily separated, and he made choice of oxygenated muriatic acid gas mixed with water. Cresses (lepidium sativum) in the oxygenated muriatic acid shewed germs at the end of fix hours, and in common water at the end of 32 hours. The action of the first sluid on the vegetable fibres is announced by an enormous quantity of air bubbles which cover the feeds, a phenomenon not exhibited by water till at the end of from 30 to 45 minutes. These experiments announced in Humboldt's Flora Subterranea Fribergensis, and in his Aphonisms on the chemical physiology of Plants, have been repeated by others (A). They were made at a temperature of from 12 to 15 Reaumur. In the summer of 1796, Hum-boldt began a new series of experiments, and found that by joining the stimulus of caloric to that of oxygen he was enabled still more to accelerate the progress of vegetation. He took the seeds of garden cresses (lepidium sativum), peas, (pisum sativum), French beans (phaseolus vulgaris), garden lettuce (lattuca sativa), mignonette (reseda odorata); equal quantities of which were thrown into pure water and the oxygenated muriatic acid at a temperature of 88° F. Cresses exhibited germs in three hours in the oxygenated muriatic acid, while none were feen in water till the end of 26 hours. In the muriatic, nitric (B), or sulphuric acid, pure or mixed with water, there was no germ at all: the oxygen feemed there to be too intimately united with bases of azot or sulphur, to be disengaged by the affinities presented by the fibres of the vegetable. The author announces, that his discoveries may one day be of great benefit in the cultivation of plants. His experiments have been repeated with great induftry and zeal by several distinguished philosophers. Profeffor Pohl at Dreiden caufed to germinate in oxygenated muriatic acid the feed of a new kind of euphorbia taken from Bocconi's collection of dried plants, 110 or 120 years old. Jacquin and Vander Schott at Vienna threw into oxygenated muriatic acid all the old feeds which had been kept 20 or 30 years at the botanical garden, every attempt to produce vegetation in which

(A) See Uslar's Fragments of Phytology, Plenck's Physiology, Villdenow's Dendrology, and Dictionnaire de

(B) The nitric acid, however, diluted with a great deal of water, accelerates germination also, according to Physique par Gehler. the experiments of Candolle, a young naturalist, who has applied with great success to vegetable physiology. This phenomena is the more interesting, as chemistry affords other analogies of the oxygenated muriatic acid and the nitric acid. Professor Pfals at Kiel, by pursuing Humboldt's experiments, has found that frogs suffocated in oxygenated muriatic acid gas increase in irritability, while those which perish in carbonic acid gas are less sensible of galvanism.

Gefche, had been fruitless, and the greater part of them were Briquas and Bremas, whom they consider as tribes of Cherik. stimulated with success. Even the hardest feeds yielded to this agent. Among those which germinated were the yellow bonduc or nickar tree (guilandina bonduc), the pigeon cytifus or pigeon pea (cytifus cajan), the dodonaa angustifolia, the climbing mimosa (mimosa scandens), and new kinds of the homea .- There are now shewn at Vienna very valuable plants which are entirely owing to the oxygenated muriatic acid, and which are at present from five to eight inches in height. Humboldt caused to germinate the clusia rofea, the feeds of which had been brought from the Bahama islands by Boose, and which before had resisted every effort to make them vegetate. For this purpose he employed a new process, which seems likely to be much easier for gardeners who have not an opportunity of procuring oxygenated muriatic acid: He formed a paste by mixing the seeds with the black oxyd of manganese, and then poured over it the muriatic acid diluted with water. Three cubic inches of water were mixed with half a cubic inch of the muriatic acid. The veffel which contains this mixture must be covered, but not closely shut; else it might readily burst. At the temperature of 950 the muriatic acid becomes ftrongly oxydated; the oxygenated muriatic gas which is difengaged paffes through the feeds; and it is during this passage that irritation of the vegetable fibres takes place. - Philosophical Magazine.

GESCHE EL AUBE, or GIR GIR, a species of grafs growing plentifully near Ras el Feel on the borders of Abyssinia. It begins, says Mr Bruce, to shoot in the end of April, when it first feels the humidity of the air. It advances then speedily to its full height, which is about 3 feet 4 inches. It is ripe in the beginning of May, and decays, if not destroyed by fire, very foon afterwards.

The leaf is long, pointed, narrow, and of a feeble texture. The flock from which it shoots produces leaves in great abundance, which foon turn yellow and fall to the ground. The goats, the only cattle these miferable people have, are very fond of it, and for it abandon all other food while it is within their reach. On the leaves of fome plants our author faw a very fmall glutinous juice, like to what we fee upon the leaves of the lime or the plane, but in much less quantity; this is of the tafte of fugar.

From the root of the branch arises a number of stalks, sometimes two, but never, as far as he had seen, more than three. 'The flower and feed are defended by a wonderful perfection and quantity of small parts. The head when in its maturity is of a purplish brown.

This species of grass was one of the acquisitions of our author's travels. It was not before known in Europe, nor when he published his book had the feed produced a plant any where but in the garden of the French king.

GHEYSSIQUAS, a nation of Hottentots which inhabits a diffrist of South Africa bordering on the country of Casfraria. M. Vaillant visited a horde of this people at no great distance from Orange river, as Cape, and was shewn by them a chain of mountains to for the purpose of knowing one another; but, as he the east, which extending to a distance was lost in the himself admits, this is a very improbable account of the north, and which, inhabited by their principal tribes, matter, as they would furely have adopted, like the

Caffres.

With respect to such characteristics as are not original and derived from nature, as the form of their dress, weapons, instruments of music, fondness for hunting and dancing, and the like, the Gheyfliquas do not differ from the furrounding nations, except in having adopted a particular colour for their ornaments. All the ornaments of the Gheyssiquas are white, and composed of the bones of a sheep's leg or foot, to which they give a dazzling whiteness by processes peculiar to themselves. Thus, as they fabricate their own necklaces and other articles of luxury, and have no occasiou to purchase the materials, they have no dependence on the colonies with respect to trade, except for a few neceffary articles, which they want in common with other favages. Accordingly this nation is less known and less visited than any other.

The women are well made, lively, and always ready to laugh or dance: yet, with all the gaiety of their difposition, they have the refervedness of manners to which polished nations give the names of modesty and decorum, and which, in fo warm a climate and with fuch ardent constitutions, appears to be a virtue of no eafy attainment.

Our author fays that he no where met with a nation fo truly generous. Though he had nothing to give in exchange, yet during two days that he flaid with them, he had bowls of milk brought to him as prefents, night and morning, from every hut. The chief even obliged him to accept a lamb; and though our traveller's attendants were not destitute of provisions, he would give them also several sheep with which to regale themselves; a degree of generosity of which a proper estimate can be formed only by those who know fomething of savage manners and savage penury.

The practice of semi castration prevails among the Gheyfliquas, and among them only of all the Hottentot tribes; and it prevails in all their hordes without exception. Our author convinced himself of this fact by his own eyes; for the men were so complaisant, that, if he had chosen, he might have inspected the whole horde. Many travellers have written upon the fubject of this whimfical operation; but they do not agree either as to its origin, the motives that lead to its invention, or the nations by whom it is practifed. Kolben, who fays that it commonly confits in the extraction of the left testicle, represents it as a religious ceremony, a general and facred law, with all the Hottentots indifcriminately; but this is unquestionably false. (See Hottentots, Encycl.) Others attribute it to the desire of the Gheyffiquas to render themselves more fleet in running, an effect which it furely is not calculated to produce; and some have faid that its intention is to prevent the too abundant propagation of the species. Yet Kolben, though he seems inclined to this last opinion, assirms that twins are not the less common on account of the operation. According to those whom M. Vaillant questioned on the subject, it is merely a mark of diffinction, which their ancestors, he was returning from his last African excursion to the being at war with the neighbouring nations, invented separated them from the Caffres, or at least from the Loangoes, Pomboes, and Cormantins, marks of distincthe ong. tion more easily discerned. Be this as it may, the operation among the Gheyffiquas is performed by the father, commonly at the birth of the child, though fometimes not till he has completed his third year.

GHIRGONG, the capital of Afam in Hindolfan is, according to Mr Pennant, fituated in latitude 260 30' north. He does not state its longitude. It has four gates, and the city is encompassed with a bound hedge of bamboos. 'I'lle Rajah's palace is furrounded by a causey, planted on each fide with a close hedge of bamboos, which serves instead of a wall. On the outfide there is a ditch, which is always full of water. The Rajah's feat is adorned with lattice work and carving. Within and without have been placed plates of brais, fo well polished, that when the rays of the sun strike upon them they shine like mirrors. It is an afcertained fact, that 3000 carpenters and 12,000 labourers were constantly employed in this work during two years before it was finished.

The Afiatic Refearches speak much of the wealth of Asam, and of the plenty and excellency of its natural productions, and that it abounds in all metals but tin. Gold is found in every part of the country by washing the fand of the rivers, and is one of the fources of revenue; 12,000, some fay 20,000 people, are employed in that work, each of whom has from the Rajah a certain wages. Its gum lac is excellent, and

it is very productive of filk.

Among the fruits which this country produces are mangoes, plantains, jacks, oranges, citrons, limes, pine apples, and puniala, a species of tamarind, which has such an excellent flavour, that every person who tastes it prefers it to the plum. There are also cocoa-nut trees, pepper vines, and the areca trees. The fugar cane excels in foftness and sweetness, and is of three colours, red, black, and white. There is ginger free from fibres, and betel vines. The strength of vegetation and fertility of the foil are fuch, that whatever feed is fown or flips planted they always thrive. The environs of Ghirgong furnish small apricots, yams, and pomegranates; but as these articles are wild, and not assisted by cultivation and engraftment, they are very indifferent. The principal crop in this country confifts in rice and lentiles. Wheat and barley are never fown; lignum aloes is also a production of this country. The filks are excellent, and refemble those of China, but they manufacture very few more than are required for use. They are successful in embroidering with flowers and in weaving velvet .- One of their great forests is inhabited by abundance of elephants: 6 or 700 may be taken in a year, but they are neglected by the natives, who have neither horses, camels, nor affes, such as are brought from other countries.

According to our author, "the people of Asam are a base unprincipled nation, and have no fixed religion. They follow no rule but that of their own inclination, and make their own vicious minds the test of the propriety of their actions. They do not adopt any mode of worship practifed either by heathens or Mahomedans, nor do they concur with any of the known feets which prevail among mankind; unlike the pagans of Hindostan, they do not reject victuals which have been dreffed by Moslems, and they abstain from no slesh except human. They even eat animals that have died a natural death."

On this passage, one of the ablest of our literary jour. Gibbon. nalists observes, that in justice to the people of Asam, we must remark, that the above account, extracted from the memoirs of Mir Jumla's expedition into that country, was composed by a rigid Mahomedan, at the court of that fanatical tyrant Aurengzebe. The author and his matter faw, in the Asamese, only idolaters; and, in idolaters, the meanest of mankind. Their diet, though less restricted than that of the Hindoos of Bengal, is by no means promifcuous; and their religion does not in any way differ from that of Hindostan, - as might cafily be proved by their coins, infcribed with the names of Hindoo deities.

GIBBON (Edward, Efq.), the celebrated historian of the Decline and Fall of the Roman Empire, was born at Putney in the county of Surrey on the 27th of April 1737. He was the first child of the marriage of Edward Gibbon, Efq; and Judith Porten, the youngest

daughter of a merchant of London.

The family of Gibbon appears to be ancient and honourable; and our author delights to trace his pedigree from John Gibbon architect to King Edward III. who possessed lands in the hundred and parish of Rolvenden. in the district which is now called the Weald of Kent. In that district the elder branch of the family still adheres to its native foil, without much increase or diminution of property; but the fortunes of the younger branch, from which sprung the subject of this memoir, were fluctuating. It is not, however, with his family,

but with himfelf, that we are concerned.

So feeble was his conflitution, and fo precarious his life during his childish years, that at the baptism of each of his brothers (and they were five in number) his father's prudence fucceffively repeated the name of Edward, that, in case of the death of the eldest son, this patronymick appellation might still be perpetuated in the family. His brothers and a fifter were all fnatched away in their infancy; and, in terms of affectionate gratitude, he attributes his own preservation to the more than maternal care of a maiden aunt, his mother's eldest fifter. " Many anxious and folitary days (fays he) did that dear and excellent woman confume in the patient trial of every mode of relief and amusement. Many wakeful nights did she sit by my bed side in trembling expectation that each hour would be my last. Suffice it to fay, that while every practitioner from Sloane and Ward to the Chevalier Taylor was successively summoned to torture or relieve me, the care of my mind was too frequently neglected for that of my health. Compassion always fuggested an excuse for the indulgence of the master, or the idleness of the pupil; and the chain of my education was broken as often as I was called from the school of learning to the bed of sickness."

His education feems indeed to have been far from systematical. At the age of seven he was delivered into the hands of Mr John Kirkby, who exercised about eighteen months the office of his domestic tutor, and of whom he writes in terms of respect. This man hadbeen an indigent curate in Cumberland, and when forced by diffress to leave his native country, he was introduced by his learning and his virtue to the family of Mr Gibbon, from whom he might have found at least a temporary shelter, had not an act of indiscretion again driven him into the world. One day reading prayers. in the parish church, he most unluckily forgot the name

Gibbon. of King George; and his patron, a loyal subject, difmissed him with some reluctance and a decent reward. As our author describes his ancestors as hereditary Tories, and some of them as Jacobites, we think it not improbable that Mr Kirkby may have been accustomed to omit the name of the King when reading prayers in the family; for otherwise he would have pronounced it mechanically in the church.

Be this as it may, our author, upon the dismission of his tutor, was fent to Kingston upon Thames, to a school of seventy boys kept by Dr Wooddeson and his affistants. He does not represent himself either as happy or as having made great progress at that school. The want of strength and activity disqualified him for the sports of the field; his companions reviled him for the fins of his Tory ancestors; and his studies were frequently interrupted by fickness. After a real or nominal refidence of near two years at Kingston, he was finally recalled (Dec. 1747) by the death of his mother. By this time he was well acquainted with Pope's Homer, the Arabian Nights Entertainments, Dryden's Virgil, and a translation of Ovid's Metamorphoses; and the entertainment which he received from these books gave him a taste for desultory reading.

After living a year with his maternal aunt, during which period he read many books on religious subjects too deep for the comprehension of a boy, he was in January 1749 entered in Westminster school, of which Dr John Nicoll was at that time head mafter. "There (fays he) in the space of two years, interrupted by danger and debility, I painfully climbed into the third form; and my riper age was left to acquire the beauties of the Latin and the rudiments of the Greek tongue. Instead of audaciously mingling in the sports, the quarrels, and the connections of our little world, I was still cherished at home under the maternal wing of my aunt, who now lived in College-street; and my removal from

Westminster long preceded the approach of manhood." He was first carried to Bath for the recovery of his health; then to Winchester, where he lived in the house of a physician; then to Bath again, where he read with a clergyman some odes of Horace and some episodes of Virgil; after which an unfuccessful trial was made to renew his attendance at Westminster school. "It might now be apprehended (fays he) that I should continue for life an illiterate cripple; but as I approached my fixteenth year, Nature displayed in my favour her mysterious energies: my constitution was fortified and fixed; and my disorders, instead of growing with my growth, and strengthening with my strength, most wonderfully vanished." In consequence of this he was carried to Oxford; and before he had accomplished his fifteenth year, was, on April 3. 1752, matriculated a gentleman-commoner of Magdalen college.

For the honour of that celebrated university, we would fain hope that the account which Mr Gibbon gives of Magdalen college is greatly exaggerated. IHe represents his tutors as wholly regardless of his morals or his studies. Speaking of the first and best of them, for he had two, he fays, " No plan of study was recommended for my use; no exercises were prescribed for his inspection; and, at the most precious season of youth.

whole days and weeks were fuffered to elapse without Gibbon. labour or amusement, without advice or account." We shall make no other remark on this passage, than that from gentlemen, who must have been contemporary with Mr Gibbon at Magdalen, we have received different accounts of the college; and it is furely a very fingular circumstance, that at this period of idleness, our author should have become enamoured of Sir John Marsham's Canon Chronicus, and have conceived the idea of writing an Esfay on the Age of Sefostris. Such, however, was the cale. Not only was the effay planned, but part of it was written; and though he never finished it, he declares, that his folution of some difficulties in chronology was not devoid of ingenuity; but he goes on to vility Oxford. "It might at least be ex pected (fays he), that an ecclefiaftical school should inculcate the orthodox principles of religion. But our venerable mother had contrived to unite the opposite extremes of bigotry and indifference: an heretic, or unbeliever, was a monster in her eyes; but she was always, or often, or fometimes (A), remis in the spiritual education of her own children Without a fingle lecture, either public or private, either Christian or Protestant, without any academical fubscription, without any Epifcopal confirmation, I was left by the dim light of my catechism to grope my way to the chapel and communion table, where I was admitted, without a question, how far, or by what means, I might be qualified to receive the facrament. Such almost incredible neglect was productive of the worst mischiefs. From my childhood I had been foud of religious disputation; nor had the elastic spring been totally broken by the weight of the atmosphere of Oxford. The blind activity of idleness urged me to advance without armour into the dangerous mazes of controverfy; and, at the age of fixteen, I bewildered myself in the errors of the church of Rome."

Thus anxious is our author to account for his reconciliation to the Romish church by the negligence of the tutors of his college. This event took place on the 8th of June 1753, when, at the feet of a priest in London, he folemnly, though privately, abjured the errors of herefy. An elaborate controversial epittle, approved by his director, and addressed to his father, announced and justified the step he had taken; and the old gentleman, in the first fally of passion, divulging the secret, the gates of Magdalen college were shut against the convert. It was neceffary therefore to form a new plan of education; and our young Catholic, by the advice of Mr Eliot (afterwards Lord Eliot), was fettled, on the 30th of June, under the roof and tuition of Mr Pavilliard, a Calvinist minister at Laufanne in Switzerland.

He represents his fituation there as at first extremely uncomfortable. He could not avoid contrasting a small chamber, ill contrived and ill furnished, with his elegant apartment in Magdalen college; and M. Pavilliard being entrusted with the management of his expences, he felt himself degraded from the rank of gentleman commoner to that of a school-boy. He began, however, gradually to be reconciled to his fate; and his love of reading returned, which, he fays, had been chilled by the air of Oxford. He rapidly acquired the French language; and of his tutor he fays, "My obligations

⁽A) Surely always and fometimes are words of very different import: why are they used then, in this sentence, as fynonymous?

Gion to the lessons of Mr Pavilliard gratitude will not suffer me to forget. He was endued with a clear head and a warm heart; his innate benevolence had affuaged the spirit of the church; he was rational, because he was moderate: in the course of his studies, he had acquired a just, though superficial knowledge of most branches of literature; by long practice he was skilled in the arts of teaching; and he laboured with affiduous patience to know the character, gain the affection, and open the

mind of his English pupil."

Under the tuition of this amiable preceptor he describes his progress in the French and Latin classics, in history, geography, logic, and metapliytics, as uncommonly rapid; and he allows to the fame man a handfome share of the honour of reclaiming him from the errors of popery. The various discriminating articles of the Romish creed disappeared like a dream; and, after a full conviction, on Christmas-day 1754, he received the facrament in the church of Laufanne. Thus had our author communicated with three different focieties of Christians before the completion of his eighteenth year; and as fuch changes from church to church are always dangerous, we need not wonder, that, in a mind so ill furnished as Mr Gibbon's then was for theological investigations, they paved the way for his last change to Deilm. At present, however, he suspended his religious inquiries, acquiefcing (as he fays) with implicit belief in the tenets and mysteries which are adopted by the general confent of Catholics and Protestants.

He continued to profecute his studies with ardour. Under Mr Pavilliard he learned the Greek alphabet, the grammar, and the pronunciation of the language according to the French accent, and foon made himself malter of the works of Homer, Herodotus, and Xenophon. During two winters he attended the private lectures of M. de Traytorrens, who explained the elements of algebra and geometry as far as the conic fections of the Marquis de l'Hôpital; but in mathematics he was content (he fays) to receive the passive impression of his professor's lectures, without any active exercise of his own powers. In the writings of Grotius and Puffendorf he studied the duties of a man, the rights of a citizen, the theory of justice, and the laws of peace and war, which have had some influence on the practice of modern Europe. "Locke's treatife on government, (fays he) instructed me in whig-principles, which are founded rather in reason than experience; but my delight was in the frequent perusal of Montesquieu, whose energy of style and boldness of hypothesis were powerful to awaken and stimulate the genius of the age."

We have been thus minute in our account of Mr Gibbon's studies, because it furnishes perhaps the most ufeful lesson which can be drawn from the whole history of his life. His education had been rendered irregular, and had been often interrupted by ill health and a feeble constitution; but as soon as he was able, and had an opportunity, he applied with ardour to the cultivation of letters, and his works bear witness that his labour was crowned with fuccess. "This part of his story therefore (to use the words of Johnson) well deserves

remainder in despair." SUPPL. VOL. I. Part II.

In the year 1757 Voltaire arrived at Lausanne, and Gibbon. our young student's defire to see the man who was at once a poet, an historian, and, as he deemed himself, the prince of philosophers, was ardent, and easily gratified. He was received by the vain and arrogant Frenchman with civility as an English youth, but could not boast of any peculiar notice or diffinction. "The highest gratification (fays he) which I received from Voltaire's residence at Lausanne, was the uncommon circumstance of hearing a great poet declaim his own productions on the stage. His declamation was fashioned to the pomp and cadence of the old stage; and he expressed the enthusiasm of poetry rather than the feelings of Nature."

About this time Mr Gibbon became enamoured of Mademoifelle Susan Curchod, the daughter of the minister of Crassy, in the mountains which separate the Pays de Vaud from the county of Burgundy. In terms of rapture he describes this lady as possessed of every accomplishment which could adorn her fex. She listened to the voice of truth and passion; her parents honourably encouraged the connection; and our author indulged in the dream of felicity: but on his return to England, he discovered that his father would not hear of this strange connection, and that without his confent he was destitute and helpless. "After a painful struggle (fays he) I yielded to my fate. I fighed as a lover, I obeyed as a fon, and my wound was infensibly healed by time, absence, and the habits of a new life." The lady confoled herself by giving her hand to M. Neckar, then a rich banker of Paris, afterwards the minister, and at last one of the destroyers of the French mo-

In the spring of the year 1758 our author was recalled to England. On his arrival in London he hastened to the house of his aunt, Mrs Porten, who had been the guardian of his tender years; for though his father was in town awaiting his arrival, he knew not how he should be received by a parent who had parted with him in anger, and given him a stepmother in his absence His reception was more agreeable than he expected. His father received him as a man and a friend; and the manners of Mrs Gibbon were fuch, that, after some referve on his fide, flie and he eafily adopted the tender names and genuine characters of mother and fon; and, by the indulgence of these parents, he was left at liberty to confult his own tafte or reason in the choice of place, of company, and of amusements. In London he had few acquaintances, and hardly any friends; and being accultomed to a very small society at Lausanne, he preferred the retirement of the country to the builde of that over-grown metropolis, where he found hardly any

entertainment but in the theatres.

Before he left Laufanne he had begun a work on the fludy of ancient literature, which was fuggested by the defire of juflifying and praising the object of a favourite pursuit. "In France (says he), to which my ideas were confined, the learning and language of Greece and Rome were neglected by a philosophic age. The guardian of those studies, the Academy of Inscriptions, was degraded to the lowest rank among the three royal soto be remembered. It may afford useful admonition cieties of Paris: The new appellation of Erudits was * See Le and powerful encouragement to men whose abilities have contemptuously applied to the successors of Lipsus and Differents been made, for a time, useless, and who, having lost one Casaubon; and I was provoked to hear *, that the ex. Preliminaire part of life in idleness, are tempted to throw away the ercise of the memory, their fole merit, had been super. Par D'Afeded by the nobler faculties of the imagination and the P Encyclope-

judgment. die.

Gibbon. judgment. I was ambitious of proving by my own ex- twenty, all agreeable, several handsome, and two or three Gibbon. ample, as well as by my precepts, that all the faculties of the mind may be exercised and displayed by the study of ancient literature." This laudable ambition continued; and in his father's house at Beriton in Hampshire he finished his Essai sur l'Etude de la Literature; which, after being revised by Mallet the poet and Dr Maty of the British museum, was, in 1761, published in a fmall 12mo volume.

The subjects of taste, criticism, and philosophy, which in this work came under our young author's confideration, could hardly promife much novelty of remark. Some former observations, however, he appears to have placed in a new and pleafing point of view; advancing, moreover, fome ingenious conjectures, and displaying no inconfiderable erudition. Yet, by his own account, he was at this time almost a stranger to the writers of Greece; and when he quotes them, it is probable that the quotations are given at fecond hand. To this effay was prefixed a dedication to his father in the English language, which exhibits the author himfelf in a very amiable light; but if his reputation had depended folely upon this youthful attempt, the name of Gibbon would have been lost in oblivion. Yet he feems, even in his riper years, to have been delighted with it himself, and to have confidered its merits as equal to those of his later productions; but Milton, it is faid, preferred the Paradife Regained to the Paradife Loft,

Before the publication of this effay, the author, at his own defire, had been appointed a captain in the South Hampshire militia, in which he ferved upwards of two years. At first, the company of rustic and illiterate officers, and the buftle of a military life, were extremely difagreeable to him, as they interrupted his studies; but he admits, that his military fervices, his bloodless and inglorious campaigns, as he calls them, were, on the whole, beneficial, as they brought him acquainted with English manners, English parties, and English principles, to which his foreign education and referved temper had hitherto kept him an entire stranger. In the camp and in quarters he had even found leifure, after the first feven or eight months of his fervice, to read a great deal of Greek, and to plan different historical works, to the composition of which he seems to have thought that he was born with an innate propenfity. He always talks of himself as a philosopher; but surely a more unphilosophical persuasion than this has seldom been admitted.

At the end of the war he went again abroad, and reached Paris on the 28th of January 1763, only 36 days after the disbanding of the militia in which he had borne the commission of a captain. In that metropolis he staid not long. He visited palaces, churches, gardens, and theatres, and was introduced to D'Alembert and Diderot, then confidered as at the head of French science. From Paris he proceeded to Switzerland, and once more took up his residence at his favourite Laufanne. Voltaire's impieties had forced him from that town to his own castle at Ferney, where our author once visited him, without (he fays) courting his more intimate acquaintance.

The fociety in which Mr Gibbon most delighted during his fecond refidence at Laufanne was a very fingular one. " It consisted of fifteen or twenty unmarried ladies of genteel families; the eldest perhaps about of exquifite beauty. At each other's houses they af. fembled almost every day, without the controll, or even the presence of a mother or an aunt; they were trusted to their own prudence, among a crowd of young men of every nation in Europe. They laughed, they fung, they danced, they played at cards, they acted comedies; but in the midst of this careless gaiety, they respected themselves, and were respected by the men; the invisible line between liberty and licentiousness was never transgressed by a gesture, a word, or a look, and their virgin chastity was never fullied by the breath of fcandal or fuspicion."

We readily agree with our author that this fingular institution was expressive of the innocent simplicity of Swifs manners; and we only regret that he liad not the fame respect for the ladies of his own country as for those frolic females of Switzerland. He would not, in that case, have stained some of his most brilliant pages

with obscene ribaldry.

We shall not follow him in his ramble through Italy, or repeat his remarks on the towns which he visited. It is fufficient, in fuch a sketch as this, to inform our readers, that it was at Rome on the 15th of October 1764, as he fat musing amidst the ruins of the Capitol, that the idea of his great work first started into his mind. But his original plan was circumferibed to the decay of

the city rather than of the empire.

From carrying even this contracted plan into execution he was for some years diverted. On the 25th of June 1765 he arrived from Italy at his father's house in Hampshire, and found that he had filial duties to perform which interrupted his studies and disturbed his quiet. His father had involved himself in difficulties. from which he could be extricated only by felling or mortgaging part of his estate; and to such sale or mortgage our author cheerfully confented. He regrets on this occasion that he had not "embraced the lucrative pursuits of the law or of trade, the chances of civil office or India adventure, or even the fat flumbers of the church;" and it is to be hoped that, when he thought even of flumbering in the church, he had still some faith in revealed religion. He wasted some time in planning a history of the revolutions of Switzerland, and even wrote part of it in the French language, which, by the advice of friends, he however suppressed. We next find him engaged with a friend in a Journal entitled Memoires Literaires de la Grand Bretagne, of which two volumes for the years 1767 and 1768 were published, and a third almost completed, when his friend, a native of Switzerland, was engaged, through his interest, as travelling governor to Sir Richard Worsfey, and the Journal was, of courfe, abandoned. He then entered the lifts with Warburton; whose interpretation of the tixth book of the Æneid he attacked with great petulance and with much fuccefs. The bishop of Glocester was by this time in a state of great mental decay, which was peculiarly unfortunate for our author; for had his Lordship enjoyed his pristine vigour, he would probably have given Mr Gibbon fuch a chaftisement as might have made him more modest afterwards when writing the history of the Decline and Fall of the Roman Empire.

To that great work he now fat down feriously; and the history which he gives of his preparatory studies fufficiently accounts for the inaccuracy of his quotations.

Gon. Through the darkness of the middle ages he explored his way in the annals and antiquities of Italy by the learned Muratori and other moderns; and feems to acknowledge that, from the beginning to the end of his work, he frequently contented himself with authorities furnished at second hand.

At last, in 1776, the first volume of his history was published by Cadell the bookseller and Strahan the printer; and the success of it far surpassed his expectation. The encomiums lavished on it by Dr Robertson and Mr Hume in letters to the author, and the fulfome compliments which those three eminent historians paid to each other, are melancholy specimens of lettered littleness and vanity. The second and third volumes appeared in 1781; the fourth, fifth, and fixth in 1787; and Mr Gibbon's fame was established as a historian. The work was admired both by natives and by foreigners, and translated into several of the languages of Europe. Dr Zimmermann represents the author as excelling perhaps Hume and Robertson, who were histoall the charms of historic style, are united in Gibbon: his periods are melody itself, and all his thoughts have nerve and vigour." This praise, however, must not be admitted without exception. Few writers, indeed, were possessed of fuch popular talents as our historian. The acuteness of his penetration, and the fertility of his genius, have been feldom equalled, and scarcely ever furpassed. He seizes, with singular felicity, on all the most interesting facts and situations, and these he embellishes with the utmost luxuriance of fancy and elegance of ftyle. His periods are full and harmonious; his language is always well chosen, and is frequently diffinguished by a new and peculiarly happy adaptation. His epithets, too, are in general beautiful and happy; but he is rather too fond of them. The uniform stateliness of his diction sometimes imparts to his narrative a degree of obscurity, unless he descends to the miserable expedient of a note, to explain the minuter circumflances. His style, on the whole, is much too artificial; and this gives a degree of monotony to his periods, which extends, we had almost said, to the turn of his thoughts.

A more ferious objection is his attack upon Christianity; the loose and difrespectful manner in which he mentions many points of morality regarded as important on the principles of natural religion; and the indecent allusions and expressions which too often occur in the

work.

An attack upon Christianity is not censurable merely as fuch; it may proceed from the purest and most virtuous motives: but, in that case, the attack will never be carried on in an infiduous manner, and with improper weapons; and Christianity itself, so far from dreading, will invite every mode of fair and candid difcussion. Our historian, it must be confessed, often makes, when he cannot readily find, an opportunity to Gibbon. insult the Christian religion. Such, indeed, is his eagerness in the cause, that he stoops to the most despicable pun, or to the most awkward perversion of language, for the pleasure of turning the scripture into ribaldry, or calling Jesus an impostor.

Yet of the Christian religion has Mr Gibbon himself observed, that it " contains a pure, benevolent, and universal system of ethics, adapted to every duty and every condition of life." Such an acknowledgment, and from fuch a writer, too, ought to have due weight with a certain class of readers, and of authors likewise, and lead them feriously to consider, how far it is consistent with the character of good citizens, to endeavour, by fly infinuations, oblique hints, indecent fneer, and profane ridicule, to weaken the influence of fo pure and benevolent a system as that of Christianity, acknowledged to be admirably calculated for promoting the happiness of individuals, and the welfare of fociety.

Mr Hayley, in his poetical Essay on History, after rians of the first rank. "All the dignity (he adds), a splendid panegyric on the arduous labours of his friend, laments the irreligious spirit by which he was

actuated.

Think not my verse means blindly to engage In rath defence of thy profaner page! Though keen her spirit, her attachment fond. Base service cannot suit with Friendship's bond; Too firm from Duty's facred path to turn, She breathes an honest sigh of deep concern, And pities Genius, when his wild career Gives Faith a wound, or Innocence a tear. Humility herfelf divinely mild, Sublime religion's meek and modest child, Like the dumb fon of Croefus, in the strife, Where force affail'd his father's facred life, Breaks filence, and with filial duty warm, Bids thee revere her parent's hallowed form (B)!

The part of the history which gave such offence to his own friend, as well as to the friends of the Christian religion in general, was the account which our historian has given of the progress and establishment of Christianity in the two last chapters of his first volume; in which he endeavours to prove, that the wonderful triumph of that religion over all the established religions of the earth, was not owing to any miraculous attesta-tions to its truth, but to five secondary causes which he enumerates; and that Christianity, of course, could not be of divine origin. Several auswers appeared on this occasion, written, as we may naturally suppose, with different degrees of temper and ability(c).

One of them only, Mr Davis, who had undertaken to point out various inftances of mifreprefentation, inaccuracy, and even plagiarism in his account, did our. historian condescend particularly to answer, and that in

(B) Herodotus relates, that a Persian soldier, at the storming of Sardis, was preparing to kill Croesus, whose person he did not know, and who, giving up all as lost, neglected to defend his own life. A son of the unfortunate monarch, who had been dumb from his infancy, and who never spoke afterward, found utterance in that trying moment, and preferved his father by exclaiming, 'O kill not Cræsus!'

(c) Dr Chelsum, Dr Randolph, Dr Watson (bishop of Llandass) Lord Hailes, Dr White, Mr Apthorpe, Mr

Davis, and Mr Taylor, the author of 'The Letters of Ben Mordecai.'

Gibbon. a tone of proud contempt and confident superiority. To and soon afterwards by the death, of his oldest and Gibbon this Mr Davis replied; and it is but justice to observe, that his reply bears evident marks of learning, judgment, and critical aeumen, and that he has convicted our author of fometimes quoting inaccurately to ferve a purpose. At his other answerers Mr Gibbon merely glanced, treating Dr Watson, however, with particular respect; but his posthumous memoirs shew how much he felt the attacks made on him by Lord Hailes, Dr White of Oxford, and Mr Taylor. To Dr Priestley, who, in his History of the Corruptions of Christianity, threw down his gauntlets at once to Bishop Hurd and the historian of the Roman empire, and who presented the latter with a copy of his book, declaring, at the fame time, that he fent it not as a gift but as a challenge; he wrote in fueh terms as produced a correfpondence, which certainly added not to the honour of the diffenting divine.

At the beginning of the memorable contest between Great Britain and America, our author was returned, by the interest of Mr Eliot (now Lord Eliot), for the borough of Liskeard, and supported, with many a fincere and filent vote, the rights, though not, perhaps, the interest, of the mother country. " After a fleeting illusive hope, prudence condemned me (says he) to aequiesce in the humble station of a mute. I was not armed by Nature and education with the intrepid energy of

mind and voice.

Vincentem strepitus, et natum revus agendis.

Timidity was fortified by pride; and even the fuccess of my pen discouraged the trial of my voice."

That pen, however, was useful to the ministry whom he could not support by his eloquence in the house. At the request of the Lord Chancellor and Viscount Weymouth, then fecretary of state, he vindicated, in a very able manner, against the French manifesto, the justice of the British arms, and his Memoire Fusificatif was delivered as a state paper to the courts of Europe. He was rewarded for this service with the place of one of the lords commissioners of trade and plantations; and kept it, till the board was abolished by Mr Burke's reform bill. For accepting this place he was feverely, but most unjustly, blamed by some of the leaders of the opposition, as if he had deferted a party in which he had never enlifted, and to the principles of which he was rendered inimical both by family prepoffession and by

his own judgment.

On the downfal of Lord North's administration, Mr Gibbon was of course in the opposition deprived of an office, without the falary of which he could not conveniently support the expense of living in London. The coalition was indeed foon formed, and his friends were again in power; but having nothing to give him immediately, they could not detain him in parliament or even in England. He was tired of the buffle of the metropolis, and fighed once more for the retirement of Laufanne, at which he arrived before the overthrow of the coalition ministry, and where he lived happily till the last years of his life. It was in this retreat that he wrote the fourth, fifth, and fixth volumes of his history; and he left it only for a year to superintend the publication of these volumes in London. This great work being concluded, he returned to the banks of the Leman

dearest Swiss friend. Lausanne had now lost much of Gibrana, its attraction; the French revolution had erowded it with unfortunate emigrants, who could not be cheerful themselves or excite the cheerfulness of others; and the demons of democracy had begun to poison the minds of the fober citizens with principles which Mr Gibbon had always held in abhorrence. Speaking of these principles and their effects in Switzerland, he adds, " I beg leave to subscribe my affent to Mr Burke's creed on the revolution of France. I admire his eloquence, I approve his politics, I adore his chivalry, and I can almost excuse his reverence for church establishments. While the aristoeracy of Berne protects the happiness, it is superfluous to enquire whether it be founded in the rights of men: the economy of the state is liberally supplied without the aid of taxes; and the magistrates must reign with prudence and equity, fince they are unarmed in the midst of an armed nation."

It was against the beneficent and mild government of Berne that the emissaries of France contrived to excite the difeontents of the people, by instilling into their fimple and untutored minds their own wild notions of liberty and equality. From the effects of this Gallic phrenzy, which began to be very visible so early as the beginning of the year 1792, Mr Gibbon resolved to take shelter in England, and to abandon, for some time at least, what he called his paradife at Lausanne. Difficulties intervened, and forced him to postpone his journey from week to week, and from month to month: but on receiving the accounts of Lady Sheffield's death, he haltened to administer consolation to his friend, and arrived fafe in London in the beginning of June 1793.

He continued in good health and spirits through the whole of the fummer; but his constitution had suffered much from repeated attacks of the gout, and from an incipient dropfy in his ancles. The swelling of his ancles, however, fubfided; but it was only in confequenee of the water flowing to another place; and being repeatedly tapped for a hydrocele, he at last funk under it, and died at his lodgings in St James's street, Lon-

don, on the 16th of January 1794.

To draw a character at once general and just of this extraordinary man, would be difficult perhaps to one who had enjoyed the pleasure of his acquaintance, and must be impossible to those to whom his person was a stranger. Of the extent of his erudition there can be but one opinion; but various opinions may be held respecting the accuracy of his knowledge. Lord Sheffield, who knew him well, and loved him much, affures us, that his conversation was still more captivating than his writings: but this could not refult from the brilliancy of his wit; for of wit he declares himself that he had none. His memory was capacious and retentive, his penetration uncommon, and his colloquial eloquence ready and elegant; fo that he could illustrate almost any topic of conversation from the copious stores of his own mind. From his private correspondence, and a journal not written for the public eye, he appears to have been a dutiful fon, a loyal subject, and an affectionate and fleady friend; but it is difficult to reconcile with fo much moral and political worth his unfair and unmanly fneers at the religion of his country.

GIBRALTAR is a fortress of immense strength, lake, but found his enjoyments damped by the diffress, of which a very full account has been given in the En-

evelopadia.

the natural history of the mountain on which the fortress is built, though, to men of science, that subject must be as interesting as a detail of sieges. This defect we are enabled to supply by means of Major Imrie's mineralogical description of Gibraltar, which is published in the fourth volume of the Transactions of the Royal Society of Edinburgh; and, we are perfuaded, the following abitract of that elegant memoir will afford rational entertainment to many of our readers.

"The form of this mountain is oblong; its fummit a fharp craggy ridge; its direction is nearly from north to fouth; and its greatest length, in that direction, falls very little short of three miles. Its breadth varies with the indentations of the shore, but it no where exceeds three quarters of a mile. The line of its ridge is undulated, and the two extremes are fomewhat higher than

"The fummit of the Sugar Loaf, which is the point of its greatest elevation towards the fouth, is 1439 feet; the Rock Mortar, which is the highest point to the north, is 1350; and the Signal House, which is nearly the central point between these two, is 1276 feet above the level of the sea. The western side of the mountain is a feries of rugged flopes, interspersed with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the north-west, where what are called the Lines intervene, and a narrow passage of slat ground that leads to the ifthmus, and is entirely covered with fortification. The eastern fide of the mountain mostly consists of a range of precipices; but a bank of fand, rifing from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its fouthern extremity falls, in a rapid flope from the fummit of the Sugar Loaf, into a rocky flat of confiderable extent, called Windmill Hill.

"The principal mass of the mountain rock consists of a grey, dense (what is generally called primary) marble; the different beds of which are to be examined in a face of 1350 feet of perpendicular height, which it presents to Spain in a conical form. These beds, or strata, are of various thickness, from 20 to upwards of 40 feet, dipping in a direction from east to west, nearly at an angle of 35 degrees. In some parts of the solid mass of this rock are found testaceous bodies entirely transmuted into the constituent matter of the rock, and their interior hollows filled up with calcareous spar; but these do not occur often in its composition, and its beds

are not separated by any intermediate strata

"The caves of Gibraltar are many, and some of them of great extent. That which most deserves attention and examination is called St Michael's Cave, which is fituated upon the fouthern part of the mountain, almost equally distant from the Signal Tower and the Sugar Loaf. Its entrance is 1000 feet above the level of the fea: This entrance is formed by a rapid flope of earth, which has fallen into it at various periods, and which leads to a spacious hall, incrusted with spar, and apparently supported in the centre by a large masfy stalacti tical pillar To this fucceeds a long feries of caves of difficult access. In these cavernous recesses, the formation and process of stalactites is to be traced, from the flimfy quilt-like cone, fulpended from the roof, to the robult trunk of a pillar, three feet in diameter, which

Gibi ar eyclopedia. Nothing, however, is in that article faid of rifes from the floor, and feems intended by Nature to Gibraltar. support the roof from which it originated.

"The only inhabitants of these caves are bats, some of which are of a large fize. The foil, in general, upon the mountain of Gibraltar is but thinly fown; and in many parts that thin covering has been washed off by the heavy autumnal rains, which have left the superfices of the rock, for a confiderable extent, bare and open to inspection. In those situations, an observing eye may trace the effects of the flow, but constant, decomposition of the rock, caused by its exposure to the air, and the corrofion of fea-falts, which, in the heavy gales of easterly winds, are deposited with the spray on every part of the mountain. Those uncovered parts of the mountain rock also expose to the eye a phenomenon worthy of fome attention, as it tends clearly to demonstrate, that, however high the surface of this rock may now be elevated above the level of the fea, it has once been the bed of agitated waters. This phenomenon is to be observed in many parts of the rock, and is conftantly found in the beds of torrents. It confifts of potlike holes, of various fizes, hollowed out of the folid rock, and formed apparently by the attrition of gravel or pebbles, fet in motion by the rapidity of rivers or currents in the fea.

" Upon the west side of the mountain, towards its base, fome strata occur, which are heterogenial to the mountain rock: the first, or highest, forms the segment of a circle; its convex fide is towards the mountain, and it flopes also in that direction. This stratum consists of a number of thin beds; the outward one, being the thinest, is in a state of decomposition, and is mouldering down into a blackish brown or ferruginous coloured earth. The beds, inferior to this, progressively increase in breadth to 17 inches, where the stratification rests

upon a rock of an argillaceous nature.

"This last bed, which is 17 inches thick, consists of quartz of a blackith blue colour, in the fepta or cracks of which are found fine quartz crystals, colourless, and perfectly transparent. These crystals are composed of 18 planes, disposed in hexangular columns, terminated at both extremities by hexangular pyramids. The largest of those that Major Imrie saw did not exceed onefourth of an inch in length: They, in general, adhere to the rock by the fides of the column, but are detached without difficulty. Their great degree of transparency has obtained them the name of Gibraltar diamonds."

Much has been faid of the fossil bones found in the rock of Gibraltar; and the general idea which exists concerning them is, that they are found in a petrified ftate, and inclosed in the folid calcareous rock; but this, fays Major Imrie, is a mistake, which could arise only from inaccurate observation and false description.

" In the perpendicular fiffures of the rock, and in some of the caverns of the mountain (all of which afford evident proofs of their former communication with the furface), a calcareous concretion is found, of a reddiffi brown ferruginous colour, with an earthy fracture, and confiderable induration, inclosing the bones of various animals, fome of which have the appearance of being human. These bones are of various fizes, and lie in all directions, intermixed with shells of snails, fragments of the calcareous rock, and particles of spar; all of which materials are still to be feen in their natural uncombined

Gibraltar. flates, partially scattered over the furface of the moun-These having been swept, by heavy rains at different periods, from the furface into the fituations above described, and having remained for a long series of years in those places of rest, exposed to the permeating action of water, have become inveloped in, and cemented by, the calcareous matter which it deposits.

"The bones, in this composition, have not the smallest appearance of being petrified; and if they have undergone any change, it is more like that of calcination than that of petrifaction, as the most solid parts of them generally admit of being cut and scraped down with the

fame eafe as chalk.

"Bones combined in fuch concretions are not peculiar to Gibraltar: they are found in fuch large quantities in the country of Dalmatia, and upon its coasts in the islands of Cherso and Osero, that some naturalists have been induced to go fo far as to affert, that there has been a regular stratum of such matter in that country, and that its present broken and interrupted appearance has been caused by earthquakes, or other convulsions, experienced in that part of the globe. But, of late years, a traveller (Abbé Alberto Fortis) has given a minute description of the concretion in which the bones are found in that country: And by his account it appears, that with regard to fituation, composition, and colour, it is perfectly fimilar to that found at Gibraltar. By his description, it also appears that the two mountain rocks of Gibraltar and Dalmatia confift of the same species of calcareous stone; from which it is to be prefumed, that the concretions in both have been formed in the same manner and about the same periods.

"Perhaps if the fiffures and caves of the rock of Dalmatia were still more minutely examined, their former communications with the surface might yet be traced, as in those described above; and, in that case, there would be at least a strong probability, that the materials of the concretions of that country have been brought together by the same accidental cause which has probably collected those found in the caverns of Gibraltar. Major Imrie traced, in Gibraltar, this concretion, from the lowest part of a deep perpendicular fiffure, up to the furface of the mountain. As it approached to the furface, the concretion became less firmly combined, and, when it had no covering of the calcareous rock, a small degree of adhesion only remained, which was evidently produced by the argillaceous earth, in its composition, having been moistened by rain and baked by

"The depth at which these materials had been penetrated by that proportion of stalactitical matter, capable of giving to the concretion its greatest adhesion and solidity, he found to vary according to its fituation, and to the quantity of matter to be combined. In fiffures, nairow and contracted, he found the concretion possesfing a great degree of hardness at fix feet from the furface; but in other fituations more extended, and where a larger quantity of the materials had been accumulated, he found it had not gained its greatest degree of adhesion at double that depth. In one of the caves, where the mass of concretion is of considerable size, he perceived it to be divided into different beds, each bed being covered with a crust of the stalactitical spar, from one inch to an inch and a half in thickness, which seems to indicate, that the materials have been carried in at

various periods, and that those periods have been very Gibralas remote from each other.

"At Rosia Bay, upon the west side of Gibraltar, this concretion is found in what has evidently been a cavern, originally formed by huge unfhapely maffes of the rock which have tumbled in together. The fiffure, or cavern, formed by the difruption and subsidence of those maffes, has been entirely filled up with the concretion, and is now exposed to full view by the outward mais having dropped down in consequence of the encroachments of the fea. It is to this foot that strangers are generally led to examine the phenomenon; and the composition, having here attained to its greatest degree of hardness and solidity, the hasty observer seeing the bones inclosed in what has so little the appearance of having been a vacuity, examines no further, but immediately adopts the idea of their being incased in the solid rock. The communication from this former chain, to the furface from which it has received the materials of the concretion, is still to be traced in the face of the rock, but its opening is at prefent covered by the base of the line wall of the garrifon. Here bones are found that are apparently human; and those of them that appear to be of the legs, arms, and vertebrae of the back, are scattered among others of various kinds and fizes, even down to the smallest bones of small birds. Major Imrie found here the complete jaw-bone of a sheep; it contained its full complement of teeth, the enamel of which was perfect, and its whiteness and lustre in no degree impaired. In the hollow parts of some of the large bones was contained a minute crystallization of pure and colourless calcareous spar; but, in most, the interior part confisted of a sparry crust of a reddish colour, fearcely in any degree transparent.

"At the northern extremity of the mountain, the concretion is generally found in perpendicular fiffures. The miners there, employed upon the fortifications in excavating one of those fiffures, found, at a great depth from the furface, two ikulls, which were supposed to be human; but, to the Major, one of them, if not both, appeared to be too small for the human species The bone of each was perfectly firm and folid; from which it is to be prefumed, that they were in a state of maturity before they were inclosed in the concretion. Had they appertained to very young children, perhaps the bone would have been more porous, and of a less firm texture. The probability is, that they belonged to a species of monkey, which still continues to inhabit, in confiderable numbers, those parts of the rock which are to

us inaccessible.

"This concretion varies, in its composition, according to the fituation in which it is found. At the extremity of Princes Lines, high in the rock which looks towards Spain, it is found to confift only of a reddish calcareous earth, and the bones of small birds cemented thereby. The rock around this spot is inhabited by a number of hawks, that, in the breeding feafon, neftle here and rear their young; the bones in this concretion are probably the remains of the food of those birds. At the base of the rock, below King's Lines, the concretion confifts of pebbles of the prevailing calcareous rock. In this concretion, at a very confiderable depth under the furface, was found the under parts of a glass bottle, uncommonly shaped, and of great thickness; the colour of the glass was of a dark green."

Gibi r. Major Imrie makes an apology for giving so minute a description of these fossil bones; but, in our opinion, the public is indebted to him for bestowing so much attention on a subject which all must admit to be curious, and which, from the strange inferences drawn from similar phenomena by modern philosophers, has become im-

portant as well as curious.

We cannot dismiss this article without noticing the fubterraneous galleries constructed in the rock not only for the protection of the men during a fiege, but also for placing cannon, to annoy the enemy, in fituations inaccessible but by such means. The idea of forming these galleries was conceived by the late Lord Heathfield when governor, and by him, in fome measure, carried into execution; though the plan was not completed till lately by General O. Hara. Of these galleries we have in the Monthly Magazine for April 1798 an animated account, which we shall insert in the writer's own words.

"The subterraneous galleries are very extensive, pierce the rock in feveral places and in various directions, and at various degrees of elevation; all of them have a communication with each other, either by flights of steps cut in the rock, or by wooden stairs where the

passages are required to be very perpendicular.

"The centinels may now be relieved during a fiege from one post to another in perfect fafety; whereas, previously to the constructing of these galleries, a vast number of men were killed by the Spaniards while marching to their feveral flations. The width of thefe galleries is about twelve feet, their height about fourteen. The rock is broken through in various places, both for the purpose of giving light and for placing the guns to bear on the enemy. In different parts there are spacious recesses, capable of accommodating a confiderable number of men. To these recesses they give names, fuch as St Patrick's Chamber, St George's Hall, &c. The whole of these singular structures have been formed out of the folid rock by blafting with gunpowder. Through the politeness of an officer on duty, a place called Smart's Refervoir was opened for our inspection, which is a great curiofity, and not generally permitted to be shewn. It is a spring at a considerable depth in the body of the rock, and is above 700 feet above the level of the fea; we descended into the cavern that contains it by a rope ladder, and with the aid of lighted candles proceeded through a narrow passage over crystallized protuberances of the rock till we came to a hollow, which appears to have been opened by fome convultion of Nature. Here, from a bed of gems, arises the salutary fount, clear as the brilliant of the east, and cold as the ificle. We hailed the nymph of the grot, and, prothrating ourselves, quaffed hygean nectar from her sparry urn. When restored to the light of day, we obtained, through the medium of the same gentleman, the key of St George's Hall, at which we arrived by a very intricate and gloomy path to the spacious excavation, which is upwards of an hundred feet in length, its height nearly the same. It is formed in a semicircular part of the rock; spacious apertures are broken through, where cannons of a very large calibre command the ifthmus, the Spanish lines, and a great part of the bay. The top of the rock is pierced through, so as to introduce sufficient light to enable you to view every part of it. It appears almost incredible that so large an excavation could be formed by gunpowder, without blowing up the whole of that part of the rock, and still more so, Gimbols that they should be able to direct the operations of such an instrument, fo as to render it subservient to the purpose of elegance. We found in the hall a table, placed, I suppose, for the conveniency of those who are traverfing the rock. The cloth was spread, the wine went round, and we made the vaulted roof refound with the accents of mirth and the fongs of conviviality."

These excavations are indeed very extraordinary works; but as the whole rock abounds with caverns, we wish that our author had inquired more particularly than he feems to have done, whether St George's Hall be wholly the work of art. From one of the paffages which we have extracted from Major Imrie's memoir, we are led to think that it is not, or, at least, that the concretion removed had not acquired the confiftence of the more folid parts of the rock. If this was the case, much of the wonder will vanish, since the pick-axe and chifel were probably employed to give elegance to the vault, and even, in some degree, to direct the operation. of the gunpowder.

GIMBOLS, are the brass rings by which a feacompass is suspended in its box that usually stands in

GIRT, in timber-measuring, is the circumference of a tree, though some use this word for the quarter or 4th part of the circumference only, on account of the great use that is made of it; for the square of this 4th part is effeemed and used as equal to the area of the fection of the tree; which square therefore multiplied by the length of the tree, is accounted the folid content. This content, however, is always about onefourth part less than the true quantity; being nearly equal to what this will be after the tree is hewed fquare in the usual way: so that it seems intended to make an allowance for the squaring of the tree.

GIRT-Line, is a line on the common or carpenter's fliding rule, employed in casting up the contents of

trees by means of their girt.

GLASS ETCHING, or Engraving upon, is in the article CHEMISTRY (Encycl.) faid to be a new art; and as that acid which diffolves filiceous earth, and also glass, was first discovered in the year 1771 by Scheele, one might naturally imagine that the art of etching with it upon glass could not be older. By many others, as well as by us, it has indeed been noticed as a new invention; yet Professor Beckmann, whose laborions refearches have brought many things to light, has proved, that so early as the year 1670 the art of etching upon glass was discovered by Henry Schwanhard, fon of George Schwanhard, who was a celebrated glass-cutter, patronized by the Emperor Ferdinand III. about the middle of the last century. At the time of his death, 1667, the father practifed his art at Prague and Ratisbon. Whether the son followed the same business at the same towns, or removed to Nuremberg, is not very evident from the professor's history; but in the year above mentioned, some aqua regia (nitro-muriatic acid) having accidentally fallen on his spectacles, he was surprised to find the glass corroded by it, and become quite foft. He thus found himself in possession of a liquid by which he could etch writing and figures upon plates of glass.

Such is our information; but if it be admitted (and it would display unreasonable scepticism to question it), Schwanhard must either have improved the nitro-muriatic

acid by fome means or other unknown to us, or have Gloff com- confined his etchings to some particular kinds of glass; for the fluoric is the only acid, with which we are acquainted, that corrodes all glass. (See CHEMISTRY-Index in this Supplement). M. Beckmann indeed seems to think that he had discovered the fluoric acid itself; for in the year 1725 there appeared in a periodical work the following receipt for making a powerful acid, by which figures of every kind can be etched upon glass.

"When the spiritus nitri per distillationem has pase fed into the recipient, ply it with a strong fire, and when well dephlegmated, pour it, as it corrodes ordinary glass, into a Weldenburg flask. Then throw into it a pulverised green Bohemian emerald, otherwise called hefphorus (which, when reduced to powder, and heated, emits in the dark a green light), and place it in warm fand for 24 hours. Take a piece of glass well cleaned, and freed from all greafe by means of a ley; put a border of wax round it, about an inch in height, and cover it all over with the above acid. The longer you let it stand so much the better; and at the end of some time the glass will be corroded, and the figures which have been traced out with fulphur and varnish will appear as if raifed above the pane of glass."

That the Bohemian emerald or hefphorus mentioned in this receipt is green sparry fluor, cannot, fays the professor, be doubted; and he seems to have as little doubt of the receipt itself having passed from Schwanhard and his scholars to the periodical work of 1725, from which it has been lately inferted in the Œkonomische Encyclopedie of Krunitz. This supposition certainly acquires a confiderable degree of probability from the fimilarity of Schwanliard's method of etching to that which is here recommended, and which is fo different from what is now followed. At prefent, the glass is covered with a varnish either of isinglass diffolved in water, or of turpentine oil mixed with a little white lead, through which the figures to be etched are traced as on copper; but Schwanhard, when he had drawn his figures, covered them with varnish, and then by his liquid corroded the glass around them. His figures, therefore, when the varnish was removed, remained smooth and clear, appearing raised from a dim or dark ground; and M. Beckmann, who perfuaded fome ingenious artifts to make trial of this antient method of etching, declares, that fuch figures have a much better effect than those which are cut into the glass.

Before concluding this article, it may be worth while just to mention a proposal which has been lately made to employ glass instead of copper for throwing off prints in the rolling press. That it is possible to use glass plates of great thickness for this purpose, it would be rash to deny; but the superiority of such plates to those of copper we cannot conceive. If not broken in pieces in the rolling press, they would doubtless last longer; but the expence of them at first would probably be greater, and the engraving on them could not

GLOSSOCOMMON, in mechanics, is a name given by Heron to a machine composed of divers dented wheels with pinions, ferving to raife huge weights.

GLUCINA (A), a peculiar earth discovered by Glucin Vauquelin in the beryl and the emerald. Its general Gold properties are as follows: 1. It is white; 2. Infipid; 3. Insoluble in water; 4. Adhesive to the tongue; 5. Infufible; 6. Soluble in the fixed alkalis; 7. Infoluble in ammoniac; 8. Soluble in the carbonate of ammoniac; 9. Soluble in almost every one of the acids (except the carbonic and phosphoric acids), and forming falts of a faccharine taste; 10. Fusible with borax into a transparent glass; 11. Absorbs one fourth of its weight of carbonic acid; 12. Decomposes the aluminous falts; 13. Is not precipitable by well-faturated hydro fulphurets.

The specific characters of glucina, which are united in none of the other known earths, are: 1. Its falts are faccharine, and flightly aftringent; 2. It is very foluble in the fulphuric acid by excess; 3. It decomposes the aluminous falts; 4 It is soluble in the carbonate of ammoniac; 5. Is completely precipitated from its folutions by ammoniac; 6. Its affinity for the acids is intermediate between magnefia and alumine.

One hundred parts of beryl contain 16 of glucina; but for the best method of analyzing the beryl, and of course obtaining the earth, we must refer our readers to the article Mineralogy in this Supplement; and shall conclude this short article with a valuable and ju-

dicious remark of Vauquelin's.

" It almost always happens (fays this able chemist), in the sciences of observation, and even in the speculative sciences, that a body, a principle, or a property, formerly unknown, though it may often have been used, or even held in the hands, and referred to other fimple species, may, when once discovered, be afterwards found in a great variety of fituations, and be applied to many useful purposes. Chemistry affords many recent examples of this truth. Klaproth had no sooner discovered the different substances with which he has enriched the science, but they were found in various other bodies; and if I may refer to my own proceffes, it will be feen, that after I had determined the characters of chrome, first found in the native red lead, I easily recognized it in the emerald and the ruby. The same has happened with regard to the earth of the beryl. I have likewife detected it in the emerald; in which, nevertheless, it was overlooked both by Klaproth and myself in our first analysis: so difficult it is to be aware of the presence of a new substance, particularly when it possesses some properties resembling those already known!"

GOLD, the most perfect of all the metals. See CHEMISTRY-Index in this Supplement.

It has been a very common opinion among metallurgifts, that tin has the property of destroying the ductility of gold, on being melted with it even in very small quantities; and Dr Lewis adds, that even the vapours which arise from tin in the fire, make gold so brittle, that it flies in pieces under the hammer. This opinion was controverted by Stanesby Alchorne, Esq; of his Majesty's mint, who made a set of experiments, which, in his opinion, authorife a very different conclufion, viz. that though tin, like other inferior metals,

(A) This name was given to the earth of beigh by the editors of the Annales de Chemi. Its most characte-fweet. According to this etymology, should not the name be Glycina?

will contaminate gold in proportion to the quantity mixed with it, yet there does not appear in tin any thing specifically inimical to that precious metal.

As we have elsewhere (See CHEMISTRY, no 1091, &c. Encycl.) enumerated these experiments, and at mitted the conclusion drawn from them, it becomes our duty, in this place, to state what has been urged

against that conclusion.

M. Tillet, being in his own mind persuaded that tin renders gold fo brittle that it cannot be reduced to thin leaves, and far less be made to pass through the wire plate but by virtue of repeated annealing, and peculiar treatment, which gold of the usual ductility does not require, determined, from respect to M. Al.

chorne, to repeat his experiments.

Mirrof His first experiment * consisted in mixing 24 grains the idemy of fine gold with one of tin which contained no arfeof S ces at nic. He wrapped the grain of tin in the 24 grains of gold reduced to a very thin leaf, and placed the whole upon a piece of charcoal, so hollowed out as to support the mixed metal during fusion. He even sprinkled a fmall quantity of calcined borax upon the metal, in order that the fusion might be more sudden, that the metal might flow together, and the tin unite with the gold, without allowing time for it to become calcined. This alloy was fpeedily fused by the enameller's lamp, and reduced into a small button without any loss of weight. It was then flattened carefully beneath the hammer; but, notwithstanding his utmost precaution in this respect, it cracked, and at last broke into three pieces, its thickness then being a quarter of a line or thereabouts. He repeated this experiment with a double quantity as well of pure gold as of tin, and the refult was the fame.

He next alloyed 4 ounces of gold, of the fineness of 22 carats, with 1 gros 24 grains of tin deprived of arfenic, or, in other words, with 4 pennyweights of tin; and these two metals being reduced into small pieces, were mixed together, put into a crucible, and urged by the strong heat of a forge with two pair of bellows. When their fusion appeared to be complete, he poured the metal into a fmall ingot mould proportioned to the

quantity.

The ingot thus obtained had lost scareely any thing of the weight of the two metals that composed it; which was a proof that the tin had united and incorporated with the four ounces of gold. But on attempting to bend the ingot, which was about fix inches long, and not more than two or three lines thick, he remarked, contrary to the nature of gold of 22 carats, that it was rigid, and would have required a confiderable effort to give it any degree of curvature, or bring it to the flexibility it would have possessed if no tin had entered into its composition. Not satisfied, however, with the inference naturally flowing from this circumstance, he proceeded to the proper test by hammering, particularly with the edge of the hammer, in order that the bar might be lengthened, and by that means submitted to the most decisive proof. He did not obferve, during the continuation of this process, till the bar was reduced to about two-thirds of its first thickness, that its edges were cracked, or exhibited much of the appearance of brittleness; but as he was apprehenfive that this accident might happen by too long

which had been hammered out. This part was placed Gold. in the midst of lighted charcoal, in order that, by a moderate annealing, it might recover the state of malleability it possessed before it was hammered. But when he went to take it out of the fire, where it had undergone no greater heat than a cherry-red, he found it divided into two parts. After having suffered these to cool, he forged them again. They were extended with confiderable eafe, though with some craeks at the edges; but they did not yet fatisfy the whole of his enquiries. He therefore annealed one of the two last mentioned pieces a feeond time, and referved the other in its hard-hammered state to be passed between the laminating rollers. The annealed part, which might have the thickness of about a shilling, breke in the fire, though the heat was very gentle, into four or five portions. The longest of these portions, which best resisted the action of the fire, bent and twifted itself, and shewed, by this state of strong contraction in different directions, that it had tended to break and become divided into small portions, similar to those which had already separated from it.

Satisfied by this experiment that the piece of the mixed ingot which he had kept in its hammer-hardened state would not bear annealing, he determined to extend it still more between the rollers, fetting them up very gradually, in order that the fracture, if it should take place, might be principally owing to the brittlenels of the material, and not to the force of compreffion to which it was subjected. By this management he succeeded in extending the metal to double its length notwithstanding its hardness, and rendering it as thin as strong paper; though the edges were cracked through their whole length like the teeth of a saw. But this accident is not at all furprifing, when it is confidered that gold, though alloyed fimply with eopper, whatever may be the cause, does not posses its usual ductility, particularly when it is laminated very thin, without repeated annealing as the metal becomes hard.

Aware that the fracture of the pieces of gold might be attributed to an incomplete fusion, or unequal mixture of the two metals, he melted the whole ingot over again with the utmost precaution; but in vain. The metal was as brittle as formerly, and would not bear annealing.

He next fused 6 ounces of pure gold of 24 earats with 2 gros, or 6 penny-weights of tin, taking every possible precaution to have the metals completely mixed. When the whole was in perfect fusion, he poured the mixture into an ingot mould, and obtained an ingot rather longer and cleaner than the two former. As foon as it was cold he forged one of its extremities with the edge of the hammer. It was lengthened without any perceptible crack; and when it was reduced to the thickness of one line, or thereabouts, he cut it off for separate treatment. By moderate annealing it maintained its integrity; and, with the exception of a few cracks, it passed the laminating rollers without breaking. As he was fearful, nevertheless, that it might break in some part if he continued to laminate it, he gave it a flight annealing. It had fearcely acquired a cherry-redness between the chareoal, before it broke into five or fix parts, some of which were fimply bended or twifted, and others flat as they quithammering, he divided the bar by cutting off the part ted the rollers. Among the annealed pieces of this Suppl. Vol. I. Part II.

Gold. extremity of the ingot, there was one sufficiently long, though a little curled, which he laminated a fecond time, with the determination of rendering it very thin without the least annealing. It acquired at least double the length it had at first without breaking; and, if we except the two fides of this plate which were cracked, the body, or main piece, was entire. It was spongy, and might be considered as if formed out of an ingot of common gold containing no tin, but not possessing

the whole of its natural ductility.

"It follows, fays M. Tillet, from these experiments, that gold, whether fine or alloyed, when perfectly fused with a small portion of the finest tin, acquires rigidity and hardness by the mixture; that it loses somewhat of its distinguishing colour; and that it may, indeed, by careful management, be extended to a certain degree by the hammer, or still better by the rollers; but that, as it cannot be annealed without danger of breaking, it is by this defect deprived of the effential advantage of recovering its original foftness after it has been strongly hammer hardened. It is not but by careful management in the use of the hammer, and by frequent annealing, that artists employed on works of gold and filver fucceed in obtaining them without cracks, and bringing them to a flate of perfection, without being obliged to have recourse to folder to repair the defects which excessive hardness under the hammer would occasion. How much, therefore, ought gold-workers, who continually have this metal in their hands, to be attentive to prevent the introduction of tin in their workshops, and never to employ such compounds of gold as are subject to break, or even to warp, while annealing? The expence of refining, which they would pay for depurating fuch compounds, would be of less consequence to them than the loss of time required for the careful management of such gold contaminated by tin, even if they did succeed in using it, and were not often forced to abandon, after much labour, a work nearly finished.

" If it be allowable (continues our author) to form conjectures on the cause of the fracture of plates of gold containing tin, when subjected to the annealing heat, it may be prefumed, fince tin very speedily melts, while gold requires a strong heat for its fusion, that the parts of the tin intermixed in a fort of proportional equality with those of the gold, tend to separate by a speedy fusion and at a very gentle degree of heat; that they remain without confistence between the parts of the gold, while the latter preferve the whole of their folidity, and do not lose it even by the annealing heat: whence it feems, that the parts of the precious metal, when ignited among the coals, having no longer the folid connection formed by the tin, but, on the contrary, having an infinite number of fmall cavities occupied by particles of that metal in fusion, must tend to disunion; whereas the same accident does not take place in the pieces which have refifted the annealing, and have been laminated after cooling, because the particles of tin have become folid by cooling, and have recovered their original state of union with the gold.

"This fracture of the compound does not take place with an alloy of gold and copper, for an opposite reason to that which has here been explained; namely, because these two metals require nearly the same heat for their fusion. The effect of annealing being therefore equal upon both, the metals, notwithilanding this Gold treatment, preserve their natural confistence, even tho' Goldon

the heat be carried near the point of fusion."

GOLD-Leaf. See Gold-LEAF (Encycl.) where a full account is given from Dr Lewis of the process of gold-beating. In that article, we have faid that goldleaf ought to be prepared from the finest gold; but Mr Nicholfon, who, in all probability, knows much more of the matter than the author from whom our account was copied, affures us that this is a miftake, and that pure gold is too ductile to be worked between the goldbeaters' skin. 'The newest skins will work the finest gold, and make the thinnest leaf, because they are the smoothest. Old skins, being rough or foul, require coarfer gold. The finer the gold, the more ductile; infomuch that pure gold, when driven out by the hammer, is too foft to force itself over the irregularities, but would pass round them, and by that means become divided into narrow flips. The finest gold for this purpose has three grains of alloy in the ounce, and the coarfest twelve grains. In general, the alloy is fix grains, or one eightieth part. That which is called pale gold contains three pennyweights of filver in the ounce. The alloy of leaf gold is filver, or copper, or both, and the colour is produced of various tints ac-Two ounces and two pennyweights of gold is delivered by the mafter to the workman, who, if extraordinarily skilful, returns two thousand leaves, or eighty books of gold, together with one ounce and fix pennyweights of waste cuttings. Hence one book weighs 4.8 grains; and as the leaves measure 3.3 inches in the side, the thickness of the leaf is one two hundred and eighty two thousandth part of an inch.

The yellow metal called Dutch gold is fine brafs. It is faid to be made from copperplates, by cementation with calamine, without subsequent suston. Its thickness, compared with that of leaf gold, proved as 19 to 4, and under equal furfaces it is confiderably more than twice as heavy as the gold. Nicholfon's

Fournal, Vol. 1ft.

GOLDONI (Charles), was born at Venice in the year 1707. He gave early indications of his humour. ous character, as well as his invincible propenfity to those studies which have rendered his name immortal. His father, perceiving that the darling amusement of his fon was dramatic performances, had a fmall theatre erected in his own house, in which Goldoni, while yet an infant, amused himself with three or four of his companions, by acting comedies. Before he was fent to school, his genius prompted him to become an author. In the feventh and eighth years of his age, ere he had fcarcely learned to read correctly, all his time. was devoted to the perufing comic writers, among whom was Cicognini, a Florentine, little known in the dramatic commonwealth. After having well studied these, he ventured to sketch out the plan of a comedy, which needed more than one eye-witness of the greatest probity to verify its being the production of a child.

After having finished his grammatical studies at Venice, and his rhetorical studies at the Jesuit's college in Perugia, he was fent to a boarding-school at Rimini, to fludy philosophy. The impulse of nature, however, superseded with him the study of Aristotle's works, so much in vogue in those times. He frequented the theatres with uncommon curiofity; and paffing

miliar acquaintance with the actors. When the sea- rate edition of these was published, under the title of fon of comic performances was over, and the actors The New Comic Theatre: among these was the Tewere to remove to Chiozza, young Goldoni made his rence, called by the author his favourite, and judged to escape in their company. This was the first fault he be the master-piece of his works. He made another committed, which, according to his own confession, journey to Parma, on the invitation of Duke Philip, drew a great many others after it. His father had in- and from thence he passed to Rome. He had comtended him to be a physician, like himself: the young posed 59 other pieces so late as the year 1761, five of man, however, was wholly averfe to the study. He proposed afterwards to make him an advocate, and sent him to be a practitioner in Modena. An horrid ceremony of ecclefiaftical jurifdiction, at which he was prefent, inspired him with a melancholy turn, and he determined to become a capuchin.

His father, perceiving the whimfical, inconftant humour of his fon, feigned to fecond this proposal, and promifed to go and present him to the guardian of the capuchins in Venice, in the hope that after some flay in that extensive and merry city, his melancholy fit would ceafe. The scheme succeeded; for the young man, indulging in all the fashionable dissipation of the place, was cured of his foolish resolution. . It was however necessary for him to be settled in some employment; and he was prevailed upon by his mother, after the death of his father, to exercise the profession of a lawyer in Venice. By a sudden reverse of fortune he was compelled to quit at once both the bar and Venice. He then went to Milan, where he was employed by the resident of Venice in the capacity of secretary; where becoming acquainted with the manager of the theatre, he wrote a farce, entitled, Il Gondoliere Veneziano, the Venetian Gondolier; which was the first comic production of his that was performed and printed. Some time after, Goldoni broke with the Venetian refident, and removed to Verona.

There was in this place, at that time, the company of comedians of the theatre of St Samuel of Venice, and among them the famous actor Cófali, an old acquaintance of Goldoni, who introduced him to the manager. He began therefore to work for the theatre, and became infenfibly united to the company, for which he composed several pieces. Having removed along with them to Genoa, he was for the first time seized with an ardent passion for a lady, who soon afterwards became his wife. He returned with the company to Venice, where he displayed, for the first time, the powers of his genius, and executed his plan of reforming the Italian stage. He wrote the Momolo, Courtifan, the Squanderer, and other pieces, which obtained universal admination.

Feeling a strong inclination to reside some time in Tufcany, he repaired to Florence and Pifa, where he wrote The Footman of Two Masters, and The Son of Harlequin lost and found again. He returned to Vein 10 vols. 8vo. As he wrote afterwards a great num- of use to render himself master of the French language.

Gol vi. gradually from the pit to the stage, entered into a fa- ber of new pieces for the theatre of St Luca, a sepa- Goldoni. which were defigned for the particular use of Marque Albergati Capacelli, and confequently adapted to the theatre of a private company. Here ends the literary life of Goldoni in Italy.

Through the channel of the French Ambassador in Venice, he had received a letter from Mr Zenuzzi, the first actor in the Italian theatre at Paris, containing a proposal for an engagement of two years in that city. He accordingly repaired to Paris, where he found a select and numerous company of excellent performers in the Italian theatre. They were, however, chargeable with the fame faults which he had corrected in Italy; and the French supported, and even applauded in the Italians, what they would have reprobated on their own ftage. Goldoni wished to extend even to that country his plan of reformation, without confidering the extreme dissiculty of the undertaking. Scurrilities and jests, which are ever accompanied by actions, geftures, and motions, are the same in all countries, and almost perfectly understood even in a foreign tongue: while the beauties of fentiment and dialogue, and other things which lead to the understanding of characters and intrigues, require a familiar acquaintance with the tongue of the writer.

The first attempt of Goldoni towards his wished-for reform, was the piece called The Father for Love; and its bad fuccess was a sufficient warning to him to defift from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general tafte, and published twenty four comedies; among which The Love of Zelinda and Lindor is reputed the best.

The term of two years being expired, Goldoni was preparing to return to Italy, when a lady, reader to the dauphiness, mother to the late king, introduced him at court, in the capacity of Italian master to the princesses, aunts to the king. He did not live in the court, but reforted there at each summons, in a postchaife fent to him for the purpose. These journeys were the cause of a disorder in the eyes, which afflicted him the rest of his life; for being accustomed to read while in the chaife, he loft his fight on a sudden, and in spite of the most potent remedies, he could never afterwards recover it entirely. For about fix months lodgings were provided him in the chateau of Verfailles. The death, however, of the dauphin, changed the face nice, and fet about executing more and more his fa- of affairs. Goldoni lost his lodgings, and only, at the vourite scheme of reform. He was now attached to end of three years, received a bounty of 100 louis in a the theatre of St Angelo, and employed himself in gold box, and the grant of a pension of four thousand writing both for the company and for his own pur- livres a-year. This settlement would not have been writing both for the company and for his own pur- livres a-year. This fettlement would not have been poses. The constant toils he underwent in these en- fusficient for him, if he had not gained, by other means, gagements impaired his health. He wrote, in the farther fums. He wrote now and then comedies for course of twelve months, fixteen new comedies, be- the theatres of Italy and Portugal; and, during these fides forty-two pieces for the theatre; among these occupations, was desirous to shew to the French that many are confidered as the best of his productions. he merited a high rank among their dramatic writers. The first edition of his works was published in 1753, For this purpose, he neglected nothing which could be

. Goldoni, He heard, spoke, and conversed so much in it, that, in the neighbouring plantations, where the women could Good Hop Good-Hope his 62d year, he ventured to write a comedy in French, and to have it represented in the court theatre, on the

occasion of the marriage of the king.

This piece was the Bourru Bienfaisant; and it met with fo great fuccess, that the author received a bounty of 150 louis from the king, another gratification from the performers, and confiderable fums from the booksellers who published it. He published, soon after, another comedy in French, called L'Avare Fastueux. After the death of Louis XV. Goldoni was appointed Italian teacher to the Princess Clotilde, the present princess of Piedmont; and after her marriage he attended the late unfortunate Princess Elizabeth in the fame capacity.

The approach of old age obliged him to quit Verfailles, and to live in Paris, the air of which, less sharp, was better adapted to his constitution. The last work of Goldoni was The Volponi, written after his retirement from court; from which time he bade a lasting adieu to writing. Unfortunately for him, he lived to fee his pensions cut off at the revolution, like others, and he spent his last days in poverty and distress. He died in 1792, at a criffs when, according to the expression of a deputy in the Convention, the French nation was

ready to repay him every debt of gratitude.

Goldoni is on a par with the greatest comic poets of modern times, with regard to dramatic talents, and is thought fuperior to them all with regard to the fertility of his genius. His works were printed at Leg-horn in 1788-91, in 31 vols. 8vo. He has been generally called the Moliere of Italy; and Voltaire, in one of his letters to Marquis Albergati, styles him The Painter of Nature. Goldoni is one of those authors whose writings will be relished in the most remote

countries, and by the latest posterity.

GOOD HOPE, or CAPE OF GOOD HOPE, was taken by the British on 17th August 1796 with very little difficulty. At this we need not be much surprised, if to the discontent which must have prevailed among the planters and townsmen with the new order of things, be added the manners of the people. M. Vaillant, who was at the Cape during the last war, when the garrison expected to be every day attacked by a British squadron, and when the people were not absolutely disgusted with their own government, represents them, however, as rendered so completely frivolous by imitating the manners of their French allies, that, though the place was strongly fortified, it could hardly be expected to hold out long against a vigorous and well conducted fiege.

" The females of the Cape (fays he), when I faw them for the first time, had really excited my astonishment by their drefs and their elegance; but I admired in them, above all, that modesty and referve peculiar to the Dutch manners, which nothing as yet had cor-

"In the course of fix months, a great change had taken place. It was no longer the French modes that they copied; it was a caricature of the French. Plumes, feathers, ribbons, and tawdry ornaments heaped together without taste on every head, gave to the prettiest figures a grotesque air, which often provoked a smile when they appeared. This mania had extended to

scarcely be known. A mode of dress entirely new was everywhere introduced; but so fantastical, that it would have been difficult to determine from what country it had been imported."

At that time a French and a Swiss regiment were in the garrison; and though the town was occupied only with warlike preparations, and though an attack from the British fleet was every moment expected, the French officers had already introduced a tatte for pleafure. Employed in the morning at their exercise, the French foldiers in the evening acted plays. A part of the barracks was transformed into a theatre; and as women capable of performing female characters could not be found in the town, they affigned these parts to fome of their comrades, whose youth, delicate features, and freshness of complexion, seemed best calculated to favour the deception. These heroines, of a new kind, heightened the curiofity of the spectators, and rendered the entertainment still more lively and interesting.

To add to the general pleafure, ladies of the first rank confidered it as incumbent on them to lend to the military actors and actreffes, their laces, jewels, rich dreffes, and most valuable ornaments. But some of them had cause to repent of their condescension; for it happened more than once that the Countess of Almaviva having left in pledge at the futtling house her borrowed decorations, the owner, to recover them, was obliged to discharge not only the bill due for brandy and tobacco, but all the other debts of the heroine.

During the intoxication and giddiness occasioned by these amusements, Love also did not fail to act his part; and certain little intrigues were, from time to time, brought to light, which gave employment to the tongue of scandal, and introduced unhappiness into samilies. Hymen, it is true, amidst these adventures, fometimes intervened to repair the follies of his brother; and many marriages, which restored every thing to order, were the refult of his negotiations; but the complaints, though stifled, did not less exist. The watchfulness of the mother was alert. The husband, by fo much the more fecretly irritated as he faw himfelf obliged to conceal his jealoufy, curfed in his heart both actors and theatre; while the matronly part of the community, less on the referve, declaimed with bitterness against the licentiousness that prevailed, which they wholly imputed to this mode of theatrical entertainment. At last, to the great mortification of the young, but to the high satisfaction of the old women and husbands, the theatre was on a sudden shut up. The cause that effected this was altogether foreign to the complaints that were made, and of a nature that it was impossible to foresee. Two of the French actors, who, it must be remembered, were officers in the army, thought proper to imitate the paper money of the company, and to put their forged notes in circulation. The forgery was detected, and traced to its authors; the two theatrical heroes were banished from the Cape; and the company, ashamed of the adventure, dared neither feek others to supply the vacant places, nor refume their stage entertainments.

Intoxicating as were these pleasures, government meanwhile had not been inattentive to the danger which threatened the colony. As they daily expected

the means of defence, and ordered different works and new fortifications to be constructed.

At first, the business was carried on with activity and ardour; because the inhabitants, instigated by their private interest, which was then considered as involved with that of the public, had voluntarily offered their services, and mingled with the workmen. Young and old, soldiers and magistrates, sailors and planters, all soldiered the honour of co-operating for the general good and common safety. To behold this heterogeneous multitude—some loaded with pick-axes, and some with spades, or other similar implements—marching out in the morning from the town, and proceeding in high spirits to the new fortifications, was a sight truly admirable.

But this patriotic fervour was of no long continuance. Under pretence of sparing their strength, and that they might not weary themselves to no purpose, they soon caused their slaves to follow them with the tools and instruments. In a little time they contented themselves with sending their slaves only; and at last these substitutes themselves, in imitation of their masters, or perhaps by their secret orders, gave over going also. Their enthusiasm, in short, from the first moment of its breaking out till the period when it was thus entirely cooled, had been the affair of something

less than a fortnight.

This taste for frivolity which, almost twenty years ago, was introduced among the Dutch in Cape-town by their good friends the French, spread rapidly thro' the planters, who are thus described by M. Vaillant, who certainly had the best opportunities of knowing

The planters of the Cape may be divided into three classes; those who reside in the vicinity of the Cape, within a distance of five or six leagues; those who live farther off in the interior parts of the colony; and lastly, those who, more distant still, are found at the extremity of the frontiers among the Hottentots.

The first, who are opulent proprietors, and have handsome country houses, may be likened to what was formerly called in France petits feigneurs terriers, and differ extremely from the other planters in ease and luxury, and particularly in their manners, which are haughty and difdainful. Such is the refult of wealth. The fecond, fimple, kind, hospitable, are cultivators, who live upon the fruits of their labour. Here we have an example of the good effects of mediocrity. The last, poor enough, yet too indolent to derive subsistence from the foil, have no other refource than the produce of some cattle, which they feed as they can. Like the Beduin Arabs, they think much of the trouble of driving them from canton to canton, and from one patturage to another. This wandering life prevents them from building any fettled habitations. When their flocks oblige them to fojourn for a while in the fame place, they construct, in haste, a rude kind of hut, which they cover with matts, after the manner of the Hottentots, whose customs they have adopted, and from whom they in no respect differ, but in their complexion and features. And here the evil is, that there is no precise situation in social life to which these miserable beings belong.

These sluggish tribes are held in horror by their in-

dustrious neighbours, who dread their approach, and remove as far from them as they can; because, having no property of their own, they steal without scruple that of others, and, when in want of passurage for their cartle, conduct them secretly to the first cultivated piece of ground that comes in their way. They stater themselves they shall not be discovered, and they remain till every thing is devoured. If detected in their thests, squabbles and contentions ensue, and afterwards a suit at law, in which recourse is had to the magistrate, and which commonly terminates in making three men enemies, the robber, the person robbed, and the judge.

Nothing can be so mean and cringing as the conduct of the first description of planters, when they have any thing to transact with the principal officers of the company, who may have fome influence over their lot; and nothing so absurdly vain and so superlatively insolent as their behaviour to persons from whom they have nothing to hope and nothing to fear. Proud of their wealth, spoiled by residing near a town, from whence they have imbibed only a luxury that has corrupted, and vices that have degraded them, it is particularly towards strangers that they exercise their surly and pitiful arrogance. Though neighbours to the planters who inhabit the interior of the country, you must not suppose they regard them as brethren; on the contrary, in the true spirit of contempt, they have given them the name of Rauw-boer, a word answering to the lowest description of clown. Accordingly, when these honest cultivators come to the town upon any kind of business, they never stop by the way at the houses of the gentry of whom we are speaking; they know too well the infulting manner in which they would be received. One might suppose them to be two inimical nations, always at war, and of whom some individuals only met at distant intervals, upon business that related to their mutual interests.

What is the more difgusting in the insolence of these Africans is, that the majority of them are descended from that corrupt race of men, taken from prifons and hospitals, whom the Dutch company, defirous of forming a fettlement at the Cape, fent thither to begin, at their risk and peril, the population of the country. This shameful emigration, of which the period is not fo remote but that many circumstances of it are remembered, ought to render particularly modest those who are in the most distant manner related to it. On the contrary, it is this very idea that most contributes to their arrogance; as if they flattered themselves that, under the guife of fupercilious manners, they could hide the abjectness of their origin. If a stranger arrives at the Cape with the defign of remaining and fettling there, they conceive him to be driven from his country by the fame wretched circumstances which formerly banished their fathers, and they treat him

with the most fovereign contempt.

This melancholy failing is the more to be lamented, as the contagion has fpread through almost every relidence about the Cape, which is in reality a very charming canton. Embellished by cultivation, by its numerous vineyards and pleasant country houses, it everywhere exhibits so varied and delicious a prospect, that, were it occupied by other inhabitants, it would excite no sensations but those of pleasure.

As we advance into the country, the planters are a fort of farmers; and conflitute, by their manners, cuftonis, and occupations, a class by themselves, perfectly distinct from that we have been describing. Situated farther from the Cape, and, of consequence, not having the same opportunities for disposing of their commodities, they are less rich than the first. We see among them none of those agreeable country houses, which, placed at different distances from the town, embellish the country as we pass, and afford such charming prospects. Their habitation, which is about the fize of a large coach-house, is covered with thatch, and divided into three rooms by means of two partitions, which reach only to a certain height. The middle apartment, in which is the entrance to the house, serves at once both as a parlour and eating-room. It is there that the family relide during the day, and that they receive their tea and other vilitors. Of the two other rooms, one forms a chamber for the male children, and the other for the females, with the father and mother. At the back of the middle apartment is a farther room ferving for a kitchen. The rest of the building confifs of barns and stables.

Such is the distribution which is generally followed in the interior plantations of the colony; but nearer to the frontiers, where there does not prevail the same ease of circumstances, the habitations are much less commodious. They are merely a barn, consisting of a single room, without any division, in which the whole family live together, without separating, either day or night. They sleep upon sheep skins, which serve

them also for covering.

The drefs of these planters is simple and rustic. That of the men confifts of a check shirt, a waistcoat with sleeves, a large pair of trowfers, and a hat half unlooped. The women have a petticoat, a jacket fitted to their shape, and a little round bonnet of muslin. Unless upon extraordinary occasions, neither sex wear flockings. During a part of the year, the women even walk with their feet quite naked. The occupations of the men require that theirs should have some covering; and this covering they make from a piece of the hide of an ox, applied and shaped to the foot foon after the animal is killed, and while the hide is yet fresh. These fandals are the only article of their dress which they make themselves; the rest is the business of the women, who cut out and prepare their whole wardrobe. Though the equipment we have mentioned constitute the every-day dress of the planter, he has, however, a coat of handsome blue cloth, which he wears upon days of gala and ceremony. He has then also stockings and shoes, and is dressed exactly like an European. But this finery never makes its appearance but when he goes to the Cape; and then, indeed, is not put on till he arrives at the entrance of the town.

It is commonly in these journeys that they purchase such things as they may want to resit their wardrobe. There is, at the Cape, as well as in Paris and London, a species of old-clothes-men, who deal in commodities of this sort; and who, from their enormous prosits, and the extortion they practise, they have obtained the name of Gapse Smouse, or Cape Jews. 'These traffickers contrive, at all times, to sell their goods at a dear rate; but they vary their price in proportion as their shock is great or small; of course they bear no sixed

price; and the planter who comes from the defert, and Good H who can understand but little of this sluctuation, is sure to be duped.

On the other hand, the regular shopkeeper, who knows the probity of these farmers, and how punctual they are in the payment of their debts, exerts every effort to prevail on them to open an account with him. He tempts them by the pretended cheap price and excellent quality of his stuffs, and offers to remit the payment till their next journey in the following year. It is feldom that these people, simple and unexperienced as they are, perceive the craft that is prefented to them under this guise of kindness and civility. If they suffer themselves to be prevailed upon, they are shackled for life. Upon their return, there are new purchases to be made upon the fame conditions; and thus, year after year, always in debt, always buying without prompt payment, they become the prey of arr extortioner, who raises to himself a fortune out of their weaknefs.

It is true, these buyers, after being thus duped at the Cape, commonly return home only to make dupes of others. The cunning that has been employed to deceive them, they employ in their turn to tempt the Hottentots who are in their service. The remnants of stuff, or the frippery garments which they bring back, are fold to these unfortunate servants with so great a prosit, that commonly the wages of a year are inadequate to the payment, and they find themselves, like their masters, in debt for the year that is to come. In the end, therefore, it is the poor Hottentot that pays for the extortion at the Cape.

Custom has rendered the planters insensible to the want of fruit and pulse, though the soil is admirably adapted to the cultivation of both. The facility with which they rear their cattle makes up for this privation, as their slocks afford them plenty of provision. The chief food is mutton; and their tables are loaded with such profusion as to disgust one at the sight.

From this mode of living, cattle are in the colonies, as in other places, not only a ufeful object, but an article of the first necessity. The planter undertakes himself the care of watching over his slocks. Every evening, when they return from the field, he stands at his door, with a stick in his hand, and counts them over one by one, in order to be sure that none of them are

niffing.

People who have no other employment than a little-agriculture, and the superintendance of a flock, must have long intervals of idleness. It is thus with the planters, particularly those who live in the interior parts of the country, and who being unable, on account of their distance from the Cape, to dispose of their corn, never raise more than is sufficient for their own consumption. From the profound inaction in which they live, one would suppose their supreme felicity to consist in doing nothing. They sometimes, however, visit each other; and upon these occasions the day is spent in smoking, and drinking tea, and in telling, or listening to tales of romance, that are equal neither in merit nor morality to the story of Blue-beard.

As every man always carries with him, wherever he goes, both a pipe, and a tobacco-pouch made of the skin of the sea-calf, he is sure in these visits to have one source of amusement. When any one of the company

and, having filled, passes it to the rest. This is a civility that is never omitted. However numerous may be the party, every body fmokes: the confequence of which is a cloud, that, rifing at first to the upper part of the room, increases, by degrees, till it fills the whole house, and becomes at last so thick, that it is impossible for the smokers to see one another.

When a stranger travelling through the country is received by the master of a house, he instantly becomes a member of the family. Accustomed to a domestic life, the planters delight in the ties of affinity, and confider in the light of a relative every person whom they love. Upon entering a house, the form of falutation is, to shake hands first with the master, and then with every male perfor in the company arrived at years of maturity. If there happens to be any one whom we do not like, the hand is refused to him; and this refusal, of so common a testimony of friendship, is looked upon as a formal declaration that the vifitor confiders him as his enemy. It is not the fame with the females in the company. They are all embraced one after another, and to make an exception would be a fignal affront. Old or young, all must be kissed. It is a benefice with the duties attached to it.

At whatever time of the day you enter the house of a planter, you are fure to find the kettle and tea-things upon the table. This practice is universal. The inhabitants never drink pure water. If a stranger prefents himself, it is tea they offer him for refreshment. This is their common liquor in the interval of meals, and in one season of the year, when it often happens that they have neither beer nor wine, is their only be-

If a stranger arrives at dinner-time before the cloth is taken away, he shakes hands, embraces, and immediately feats himself at the table. If he wishes to pass the night, he stays without ceremony, smokes, drinks tea, asks the news, gives them all he knows in his turn; and the next day, the kiffing and shaking hands being repeated, he goes on his way, to perform elsewhere the fame ceremony. To offer money on these occasions would be regarded as an infult.

These particulars of a people, whose condition it is to be hoped that the generofity of the British character, and the mildness of the British government, will gradually meliorate, cannot but be acceptable to many of our readers. We shall, therefore, make no apology

for the length of this article.

GOMASHTEH, in the language of Bengal, one

cent.

GONIOMETRY, a method of measuring angles, fo called by M. de Lagny, who gave feveral papers on this method in the Memoirs of the Royal Acad. anno 1724, 1725, 1729. M. de Lagny's method of goniometry confilts in measuring the angles with a pair of compasses, and that without any scale whatever, except an undivided femicircle. Thus, having any angle drawn upon paper to be measured, produce one of the sides of the angle backwards behind the angular point; then with a pair of fine compasses describe a pretty large femicircle from the angular point as a centre, cutting the fides of the proposed angle, which will intercept a part of the femicircle. Take then this intercepted part very exactly between the points of the compasses, and turn them successively over upon the arc of the semi-

od I e is desirous of lighting his pipe, he takes out his pouch, circle, to find how often it is contained in it, after which Gothie there is commonly some remainder: then take this remainder in the compasses, and, in like manner, find how often it is contained in the last of the integral parts of the first arc, with again some remainder: find, in like manner, how often this last remainder is contained in the former; and fo on continually, till the remainder become too small to be taken and applied as a measure. By this means he obtains a feries of quotients, or fraetional parts, one of another, which being properly reduced into one fraction, give the ratio of the first arc to the femicircle, or of the proposed angle to two right angles, or 180 degrees, and confequently that angle itself in degrees and minutes.

We have given this account of goniometry from Dr Hutton, and frankly acknowledge that we had never thought of it till we peruled his excellent Dictionary of Mathematics and Philosophy. To have omitted the method when pointed out to us would have been wrong; though we miltake much if mathematicians in general will not look upon it as a method of very little value.

GOTHIC ARCHITECTURE, (See Gothic ARCHI-GOUVERNANTE, the Spanish name of a plant

which the Indians of California use in decoction as a fudorific drink for the cure of the venereal difease. It is thus described in the third volume (English translation) of Peyrouse's Voyage round the World.

Calyx quadrified, egg-shaped, of the same size with the corolla; placed beneath the fruit, deciduous. Corolla polypetalous; petals four, finall, entire, egg shaped, fixed upon the receptacle. Stamina, eight, fixed to the receptacle, of the fame length as the corolla: threads channelled, concave on the one fide, and convex on the other; wings veiled, antheræ simple. Pistil, germ oblong, covered, with five angles, and five cells; feeds oblong; pericarpium covered with fine hairs.

This plant is a shrub of middle size; the branches are angular and knotty, and covered with an adhefive varnish; the lateral branches are alternate, and placed very near to each other: the leaves are fmall, petiolated, bilobed, opposite, smooth on the upper side, the under fide indiffinctly veined; the bloffoms are axillary, fometimes terminating, pedunculated, folitary, but fometimes in pairs.

From this description, the gouvernante appears to

be a new species of daphne.

GRAVIMETER, the name given by citizen Guyton (Morveau) to an instrument of glass, constructed in all respects on the principle of Nicholson's Hydrometer, described in the article Hydrostatics, no 18 (Encycl.) It is therefore needless to give a description of this instrument here; as every artist in glass, who has feen Nicholson's Hydrometer, or understands our description of it, may construct the gravimeter of Morveau; and every man who has made himself master of our article Specific Gravity, may apply the gravimeter to every purpose to which it is applicable. It may just be proper to observe, that Morveau, having at first loaded the small scale or bason G (Plate 240, fig. 9. Encycl.) with a bulb of glass containing a sufficient quantity of mercury, found it expedient afterwards to fubilitute in the place of this bulb a fmall mass of solid glass, brought to the proper form and weight by grinding. For a minute account of this instrument, if any of our readers can be supposed to require

Green. require a minute account of it, we must refer to the third number of Nicholson's Journal of Philosophy, Chemistry, and the Arts.

GREEN, though one of the feven original or prifmatic colours, is among dyers a compound of blue and yellow. Of the European methods of dyeing green, and of the principles on which these methods are founded, a sufficient account will be found in the Encyclopædia, under the articles Colour making and DyE. ING, and, in this Supplement, under Animal and Vegetable SUBSTANCES; but it may be worth while, in this place, to infert the method practifed at Astracan, in giving to cotton yarn that beautiful green colour for which the oriental cotton is so justly admired.

The principal dye is the blue, which is employed both for cotton and filk. To prepare it, the indigo or blue dye stuff is finely pounded, and dissolved in water by a gentle heat in large earthen jars, seven of which stand in brick-work over the fire-place, at the distance of about an ell and a half from each other. About two pounds are put into each veffel. Five -pounds of foda finely pounded, together with two pounds of pure lime and one pound of clarified honey, are added to each; when these ingredients have been well mixed, the fire is strengthened; and when the -whole begins to boil, the dye is stirred carefully round in all the veffels, that every thing may be completely diffolved and mixed. After the first boiling the fire is flackened, and the dye is suffered to stand over a gentle heat, while it is continually stirred round: this is continued even after the furnace is cooled, till a thick feum arises in the neck of each jar, and soon after disappears. The dye is then allowed to stand two days, until the whole is incorporated, and the dye

The dyers affert, that with this dye they can produce three shades of blue, and that, as the dyeing parvicles gradually diminish, they can dye also a green co-

lour by the addition of yellow.

When a manufacturer gives cotton yarn to a blue dyer, he first boils it at home in a ley of soda (kalakar), then dries it, washes it, and dries it again. The blue dyer lays this yarn to steep in pure water, presses out the superfluous water with the hands, and then immediately begins to dip it in the blue jar, often wringing it till it is completely penetrated by the dye. This first tint is generally given to yarn in such jars as have had their colouring matter partly exhaufted. It is then dried, rinfed, and again dried; after which, it is put into the fresh blue dye, properly saturated; and, after the colour has been fufficiently heightened, it is dried for the last time.

For a yellow dye, the dyers of Astracan employ partly faw-wort, brought from Russia, and partly the leaves of the kiflar belge, or fumach. The process is as follows: The yarn is first boiled for an hour in a strong ley of foda; it is then dried, afterwards rinfed and laid wet to steep for twelve hours in a folution of alumwith warm water. When it has been dried in the air, it is laid to foak feveral times in troughs with the dye lour, care being taken to dry it each time it is foaked. last time.

and applied on artists and to you by about the

On this yellow colour a green is often dyed. After Green the yarn has been dyed yellow, it is given out to the blue dyer, who immediately dips it in the blue jars, the dye of which has been already partly exhaulted; and if the green colour is not then fufficiently high, the operation is repeated, the yarn being dried each time, See Neue Nordische Beytrage, by Professor Pallas; or Philosophical Magazine, nº 2.

GREGORY (David), was a fon of the Rev. John Gregory, minister of Drumoak, in the county of Aberdeen, and elder brother to Mr James Gregory, the inventor of the most common reflecting telescope. He was born about the year 1627 or 1628; and though he possessed all the genius of the other branches of his family, he was educated by his father for trade, and ferved an apprenticeship to a mercantile house in Holland. Having a stronger passion, however, for knowledge than for money, he abandoned trade in 1655; and returning to his own country, he fucceeded, upon the death of an elder brother, to the estate of Kinardie, fituated about forty miles north from Aberdeen, where he lived many years, and where thirty two children were born to him by two wives. Of these, three fons made a confpicuous figure in the republic of letters, being all professors of mathematics at the same time in three of the British universities. viz. David at Oxford, James at Edinburgh, and Charles at St Andrews.

Mr Gregory, the subject of this memoir, while he lived at Kinardie, was a jest among the neighbouring gentlemen for his ignorance of what was doing about his own farm, but an oracle in matters of learning and philosophy, and particularly in medicine, which he had fludied for his amusement, and began to practise among his poor neighbours. He acquired fuch a reputation in that science, that he was employed by the nobility and gentlemen of that county, but took no fees. His hours of study were fingular. Being much occupied through the day with those who applied to him as a physician, he went early to bed, rose about two or three in the morning, and, after applying to his studies for some hours, went to bed again and slept an hour or two before breakfast.

He was the first man in that country who had a barometer; and having paid great attention to the changes in it, and the corresponding changes in the weather, he was once in danger of being tried by the prefbytery for witchcrast or conjuration. A deputation of that body waited upon him to enquire into the ground of certain reports that had come to their ears; but he satisfied them so far as to prevent the profecution of a man known to be so extensively useful by his know-

ledge of medicine.

About the beginning of this century he removed with his family to Aberdeen, and in the time of Queen Anne's war employed his thoughts upon an improvement in artillery, in order to make the shot of great guns more destructive to the enemy, and executed a model of the engine he had conceived. Dr Reid informs us, that he converfed with a clock maker in A. which has been boiled thick in kettles from the above- berdeen who had been employed in making this model; mentioned plants, till it has acquired the wished-for co- but having made many different pieces by direction without knowing their intention, or how they were to It is then rinfed in running water, and dried for the be put together, he could give no account of the whole. After making some experiments with this mowant all to be all tops and primarile -- -

Gr 17, del, which fatisfied him, the old gentleman was fo fan- by which edge-tools are sharpened. As commonly Grinding. guine in the hope of being uleful to the allies in the practifed, the grinding of tools is attended with great war against France, that he fet about preparing a field inconveniency arising from the production or developeequipage with a view to make a campaign in Flanders, ment of heat by friction. The fact of sparks slying and in the mean time fent his model to his fon the Sa- from a dry grindstone when a piece of iron or steel is vilian professor, that he might have his and Sir Isaac applied to its surface during the rotation, has been seen Newton's opinion of it. His fon shewed it to Newton, without letting him know that his own father was is fuch that the steel very soon becomes ignited, and the inventor. Sir Isaac was much displeased with it, hard tools are very frequently softened and spoiled, for faying, that if it had tended as much to the prefervation of mankind as to their destruction, the inventor would have deferved a great reward; but as it was contrived folely for destruction, and would soon be known by the enemy, he rather deserved to be punished, and urged the professor very strongly to destroy it, and if from above, the quantity is too small to preserve the possible to suppress the invention. It is probable the requisite low temperature. It is even found, that the professor followed this advice. He died soon after, point of a hard tool, ground under a considerable mass and the model was never found.

Reid's veracity is unquestionable, we cannot help thinking that Newton's usual fagacity had, on that ocat prefent. Muskets and cannons are furely more de-diameter, and also a block of mahogany to be used structive weapons than javelines and bows and arrows; with emery on its face. Both the stone and the woodand yet, it is a well known fact, that fince the inven- en block were mounted on an axis, to be occasionally tion of gunpowder battles are not half so bloody as they were before that period. The opposite armies now feldom come to close quarters, a few rounds of the day; and had Mr Gregory's improvement been for the emery. The face of the stone was left smooth, carried into effect. still fewer rounds would have decided it than at prefent, and the carnage would confequently have been lefs.

When the rebellion broke out in 1715, the old gentleman went a fecond time to Holland, and returned when it was over to Aberdeen, where he died about

GREGORY (Dr David). In addition to the acmatician, it may be proper to add, that he was a most intimate and confidential friend of Sir Isaac Newton, and was intrusted with a manuscript copy of the Principia, for the purpole of making observations on it. Of these Newton availed himself in the second edition, they having come too late for his first publication, which was exceedingly hurried by Dr Halley, from fears that Newton's backwardness would not let it appear at all. There is a complete copy of these observations preserved in the library of the university of Edinburgh, presented to it by Dr James Gregory, the present professor of the practice of medicine. These contain many sublime mathematical discussions, many valuable commentaries on the Principia, and many interesting anecdotes. There are in it some paragraphs in the hand-writing of Huyghens relative to his Theory of Light. It would appear that this work of confidential friendship was the foundation of that fyftem of physical and mathematical astronomy which has raifed Dr Gregory to great eminence in the republic of letters.

GRINDING in Cutlery, a well-known operation, Suppl. Vol. I. Part II.

by every one. The heat produced during this process want of care during the grinding. When a cylindrical stone is partly immersed in a trough of water, the rotation must be moderate and the work slow, otherwife the water would foon be thrown off by the centrifugal force; and when this fluid is applied by a cock of water, will be softened, if it be not held so as to If this be a just account of the matter, and Dr meet the stream; sparks being frequently afforded even under the water.

To find a remedy for this, Mr Nicholfon was led, casion, forfaken him. Were the implements of war by some accounts which he received of German cutmuch more destructive than they are, it by no means lery, to make the following experiment. He procured follows that more men would be killed in battle than a Newcastle grindstone of a fine grit and ten inches in applied between the centres of a strong lathe. In this fituation both were turned truly cylindrical, and of the fame diameter. The face of the wood was grooved muskerry and artillery commonly decide the fate of obliquely in opposite directions, to afford a lodgement and there was a trough of proper fize applied beneath the stone to hold water. The grindstone was then used with water, and the wooden cylinder was faced with emery and oil. The instrument ground was a file, out of which it was proposed to grind all the teeth. The rotation was produced by the mechanism 1720, aged 93, leaving behind him a hiftory of his of the lathe; the velocity being fuch as to run the own time and country, which was never published. The stone operated but slowly, and the water from the count given in the Encyclopedia of this eminent mathetrough was foon exhausted, with inconvenience to the workman, who could scarcely be defended from it but by flackening the velocity. The emery cylinder cut rather faster. But notwithstanding the friction was made to operate fuccessively and by quick changes on the whole surface of the file, it soon became too much heated to be held with any convenience; and when a cloth was used to defend the hand, the work not only became awkward, but the heat increased to such a degree that the oil began to be decomposed, and emitted an empyreumatic fmell. The stone was then suffered to dry, and the file tried upon its face. It almost immediately became blue, and foon afterwards red-hot. Both the cylinders were then covered with tallow, by applying the end of a candle to each while revolving, and emery was fprinkled upon the cylinder of wood. The fame tool was then applied to the grindstone in rapid motion. At the first instant the friction was fearcely perceptible; but very fpeedily afterwards the zone of tallow pressed by the tool became fused, and the stone cut very fast. The tool was scarcely at all heated for a long time; and when it began to feel warm, its temperature was immediately lowered by removing

moving it to a new zone of the cylinder. The fame effect took place when the experiment was repeated

with the wooden cylinder.

It is not difficult to explain this by the modern doctrine of heat. When oil was used upon the wooden evlinder, the heat developed by the friction was employed in raifing the temperature of the tool and of the fluid oil: but when tallow was substituted instead of the oil, the greatest part of the heat was employed in fufing this confistent body. From the increased capacity of the tallow, when melted, this heat was absorbed, and became latent, instead of being employed to raife the temperature: and whenever, by continuing the process, the tallow already melted began to grow hot, together with the tool, it was eafy to reduce the temperature again by employing the heat on another zone of confishent tallow. He used these two cylinders, with much fatisfaction, in a confiderable quantity of work.

This promifes to be a valuable discovery; and the public is obliged to the ingenious author of the Philofophical Journal for being at so much pains on this, as well as on other occasions, to render his science subser-

vient to the useful arts.

GROSE (Francis, Efq; F.A.S.) was born, we believe, in 1731. He was the fon of Mr Francis Grose of Richmond, jeweller, who filled up the coronation crown of George II. and died 1769. By his father he was left an independent fortune, which he was not of a disposition to add to, or even to preserve. He early entered into the Surrey militia, of which he became adjutant and paymafter; but fo much had diffipation taken poffession of him, that in a fituation which above all others required attention, he was fo careless as to have for some time (as he used pleasantly to tell) only two books of accounts, viz. his right and left hand pockets. In the one he received, and from the other paid; and this too with a want of circumspection which may be readily supposed from such a mode of book-keeping. His losses on this occasion roufed his latent talents. With a good classical education he united a fine taste for drawing; and encouraged by his friends, as well as prompted by his situation, he undertook the work from which he derived both profit and reputation; we mean, his Views of Antiquities in England and Wales, which he first began to publish in numbers in the year 1773, and finished in the year 1776. The next year he added two more volumes to his English Views, in which he included the islands of Guernsey and Jersey, which were completed in 1787. This, work answered his most fanguine expectations; and, from the time he began it to the end of his life, he continued without intermission to publish various works (a list of which we subjoin), generally to the advantage of his literary reputation. and almost always to the benefit of his finances. His wit and good humour were the abundant fource of fatisfaction to himself, and entertainment to his friends. He vifited almost every part of the kingdom, and was well received wherever he went. In the summer of 1789 he fet out on a tour in Scotland; the refult of which he began to communicate to the public in 1790 in numbers. Before he had concluded this work, he proceeded to Ireland, intending to furnish that king dom with views and descriptions of her antiquities, in

the same manner he had executed those of Great Britain; but soon after his arrival in Dublin, being at the house of Mr Hone there, he suddenly was seized at table with an apoplectic sit, on the 6th May 1791, and died immediately. He was interred in Dublin.

" His literary history (says a friend), respectable as it is, was exceeded by his good humour, conviviality, and friendship. Living much abroad, and in the best company at home, he had the easiest habits of adapting himself to all tempers; and, being a man of general knowledge, perpetually drew out fome conversation that was either useful to himself or agreeable to the party. He could observe upon most things with precifion and judgment; but his natural tendency was to humour, in which he excelled both by the felection of anecdotes and his manner of telling them: it may be faid, too, that his figure rather affifted him, which was in fact the very title page to a joke. He had neither the pride nor malignity of authorship: he felt the independency of his own talents, and was fatisfied with them, without degrading others. His friendships were of the same cast; constant and sincere, overlooking some faults, and seeking out greater virtues. He had a good heart; and, abating those little indiscretions natural to most men, could do no wrong."

He married at Canterbury, and refided there some years, much beloved and respected for his wit and vivacity; "which (another friend observes), though he possessed in an extreme degree, was but little tinctured with the caustic spirit so prevalent among spirits of that class. His humour was of that nature which exhilarates and enlivens, without leaving behind it a sting; and though perhaps none possessed more than himself the faculty of "fetting the table in a roar," it was never at the expence of virtue or good manners. Of him indeed may be said in the words of Shake-

fpeare

Within the limits of becoming mirth, I never fpent an hour's talk withal: His eye begets occasion for his wit; And every object that the one doth catch, The other turns to a mirth-moving jest.

"Of the most careless, open, and artless disposition, he was often (particularly in the early part of his life) the prey of the designing; and has more than once (it is believed) embarrassed himself by too implicit considence in the probity of others. A tale of distress never failed to draw commiseration from his heart; and often has the tear been discovered gliding down that cheek which a moment before was stuffed with jocularity."

He was father of Daniel Grose, Esq; captain of the royal regiment of artillery (who, after several campaigns in America, was appointed in 1790 deputy governor of the new settlement at Botany Bay), and some

other children.

His works are as follow:

1. The Antiquities of England and Wales, 8 vols.
4to and 8vo. 2. The Antiquities of Scotland, 2
vols. 4to and 8vo. 3. The Antiquities of Ireland, 2
vols. 4to and 8vo. 4. A Treatife on ancient Armour
and Weapons, 4to, 1785. 5. A Classical Dictionary
of the Vulgar Tongue, 8vo, 1785. 6. Military Antiquities; being a History of the English Army from

Bite, the Conquest to the present time, 2 vols 4to, 1786, Guitne. 1788. 7. The History of Dover Castle, by the Rev. William Danell, 4to, 1786. 8. A Provincial Glosfary, with a Collection of local Proverbs and popular Superstitions, 8vo. 1788. 9. Rules for drawing Caricatures, 8vo, 1788. 10. Supplement to the Treatife on Ancient Armour and Weapons, 4to, 1789. 11. A Guide to Health, Beauty, Honour, and Riches; being a collection of humorous Advertisements, pointing out the Means to obtain those bleffings; with a suitable introductory Preface, 8vo. 12. The Olio; being a Collection of Essays in 8vo, 1793.

GUERITE, in Fortification, a centry-box; being a finall tower of wood, or stone, usually placed on the point of a bastion, or on the angles of the shoulder, to hold a centinel, who is to take care of the ditch, and

watch against a surprise.

GUILLOTINE, a new term introduced into the languages of Europe by the mournful effects of fanaticifm in the holy cause of liberty. Our readers are not ignorant that this is the name given by the National Assembly of France to the engine of decapitation, which those usurpers of the legislative authority decreed to be the fole punishment of those condemned to death for their crimes. This decree was iffued on March 20th

We do not imagine that the world will derive much useful instruction from a minute description of this terrible instrument of public justice; and therefore content ourselves with giving two figures of it, sufficiently expressive of its construction. It is only the revival of an instrument used in former times. The earliest accounts that we have of it is, that it was used in the barony of Halyfax in Yorkshire. It was also set up in Scotland; but we have no certain information that it has ever been used; and it is still shewn as a fort of curiosity by the name of the Mayden. See MAIDEN, Encycl.

Eratosthens could not think of a better way of handing down his name to future ages than by burning the temple of Diana at Ephefus; Dr Guillotin, phyfician at Lyons, and member of the self-named National Asfembly of France, thought himself honoured by the decree which affociated his name with this instrument of popular vengeance. It was indeed proposed by him as an instrument of mercy, in a studied harangue, silled with that sentimental slang of philanthropy, which costs so little, promises so much, and has now corrupted all the languages of Europe. His invention is indeed one of the most expressive specimens of Gallic philanthropy, whose tender mercies are cruel; and was accordingly received with loud applauses, both from the house and from the galleries. To proceed, however, with imposing dignity, it was referred to the confideration of a committee, with injunctions to ask the opinion of able surgeons of its efficiency. Mr Louis, a celebrated furgeon of Paris, declared it well fitted for the task, in a long pedantic differtation; in which he takes occasion to deliver, with academic coldness, a theory of the operation of cutting instruments; and fays that he had examined the edge of the guillotine, and other fuch instruments, with a microscope, and had discovered that the finest edges were toothed like a saw. M. Guillotin, he faid, had therefore with great judgment made the axe of his engine of death with a floping edge, by which means il gliffoit d'une façon infinitment plus douce.

This differtation was so much to the taste of the hu- Guillotine mane legislature, that they rewarded Mr Louis with 2000 livres, and published it in the Paris Journals. As der to the inventor, he reaped all the benefit from it which he fo kindly intended for the nation, by the trial of it on his own person, when he fell under the displeasure

of Robespierre.

We acknowledge, that in as far as this instrument leffens the duration of the horrid conflict with the king of terrors, and probably diminishes the corporeal sufferance, it may be called merciful (alas! the day!); but we question much, whether the dreadful agitation of foul is not rather increased by the long train of preparatory operations. The hands of the convict are tied behind his back: he is then stretched along on his face on a ftrong plank, and his precise position adjusted to the instrument. When fastened to the plank, it is pushed forward into its place under the fatal edge, his neck adjusted to the block, and a basket placed just before his eyes (for the face of Louis XVI. was not covered) to receive his head. This must employ a good deal of time, and every moment is terrible.

The construction has received many alterations and refinements; and has at last been made so compendious and portable, as to become part of the travelling equipage of a commissioner from the National Assembly, fent on a provincial or special visitation. 'I'has did the fovereign people become terrible in majesty. So senfible was the Assembly of the advantages of this awful impression, or so intoxicated with the enjoyment of irrefiftible power, that they have thought their coins ornamented by this attribute of their supremacy: and as Jupiter is distinguished by his thunderbolt, so the majefty of the people is diffinguished by the no less fatal axe. We have feen a piece of ten fous, struck at Mentz in 1793, and issued as current money, at the very time that they were planting the tree of liberty in that illuminated city by the hands of Custine and his troops. The device is the fasces and axe of ancient Rome, crowned with the red cap, and furrounded by a laurel wreath. The inscription is, Republique Françoise, 1793, an. 2d. Fully impressed with the same sentiments, Lequinio, the fentimental novellist of France, whom Mercier compares with the tender, the heart-touching Sterne - Lequinio, now commissioner, sent by the National Affembly to regenerate Normandy and Brittany, writes to his masters, that "he is very successful in conversions from superstition to found reason." He opposes to the Bible and the relicts of the faints the conflitution and the guillotine. "And you would wonder (fays he) at my fuccess-The wife (but they are few) give up their prejudices at once; but the multitude, the ftupid worshippers of Notre Dame, look at our lady the guillotine; are filent, become ferious, and their doubts vanish; -they are converted. This is your labarumin boc signo winces."

GULA, GUEULE, or GOLA, in Architecture, a wavy member whose contour refembles the letter S.

commonly called an Ogee.

GUNPOWDER, as we have o'sferved in the Ency. clopadia under the word Gun, has been known in the east, and particularly in China, from a period of very remote antiquity. No man, however, feems to have fuspected that the knowledge of it was conveyed from the east into Europe; but all have agreed to allow the 4 Y 2

tions of the Royal Irish

Academy.

Gunpow- merits of the invention both to friar Bacon and to there is scarcely a subject concerning which the most Gunpow-Bartholomew Schwartz. This generally received opinion has been lately controverted by citizen Langles, who, in a memoir read in the French national institute, contends, that the knowledge of gunpowder was conveyed to as from the Arabs, on the return of the Crufaders to Europe. He affures us that the Arabs made asse of it in 690 at the siege of Mecca; and he adds, that they derived it from the Indians, among whom it must have been known in the remotest ages, since their facred books (the Vedam) forbid the use of it in

It is indeed extremely probable, that the composition of gunpowder was known in India at a very early period; for in whatever country nature forms nitre in the greatest plenty, there its deflagrating quality is most likely to be first observed; and a few experiments founded on that observation, will lead to the composition which produces fuch fudden and violent effects. " Nitre (fays Sir George Staunton) is the natural and daily produce of China and India; and there, accordingly, the knowledge of gunpowder feems to be coeval with that of the most distant historic events. Among the Chinese, it has been applied at all times to useful purposes; such as blasting rocks, and removing great obstructions, and to those of amusement in making a vast variety of fire-works. It was also used as a defence, by undermining the probable passage of the enemy, and blowing him up. But its force had not been directed through strong metallic tubes as it was by Europeans soon after they had discovered it. And though, in imitation of Europe, it has been introduced into the armies of the East, other modes of warfare are sometimes still preferred to it."

Of gunpowder manufactured by those who have manufactured it fo long, it is defirable to know the composition and the qualities. It was therefore natural for the Hon. George Napier, when superintending the royal laboratory at Woolwich, and making experiments upon so necessary an implement of modern war, to procure some Chinese powder from Canton.

This he did; and analyzing two ounces of it, he found, after repeating the operation fix times, that the * Transac. mean result gave the following proportions *. Nitre 1 oz. 10 dwts. charcoal 6 dwts. fulphur 3 dwts. 14 grs. Here is a deficiency in weight of ten grains, which M. Napier supposes the consequence of some defect in his process; but as M. Banmé, a French chemift, made a variety of experiments to obtain a total feparation of the fulphur from the charcoal of gunpowder, and was never able to effect it, one fourteenth part remaining united, three grains must be deducted from the charcoal, and added to the fulphur to give the accurate proportion of the ingredients; which by turning to the article Gunpowder, Encycl. the reader will pereeive differs somewhat from the proportion of the same ingredients in the gunpowder of Europe. This Chinese powder was usually large grained, and not strong, but very durable. It had been made many years when our author got it; yet there was no visible symptom of decay, the grain being hard, well coloured, and though angular, it was even-fized, and in perfect prefervation.

When we confider the operations in which gunpowder is employed, it is obvious that it must be an object of importance to afcertain its explosive force; and yet

approved writers have so much differed. Mr Robins, who has done more towards perfecting the art of gun. nery than any other individual, states the explosive force of gunpowder to be 1000 times greater than the mean pressure of the atmosphere; while the celebrated Daniel Barnouilli determines it to be not less than 10,000 times this pressure. Such a difference of opinion led Count Rumford to pursue a course of experiments, of which some were published in the Transactions of the Royal Society for the year 1781, and the remainder in the Transactions of the same Society for 1797; with the force of gunpowder. By one of these experiments, it appeared that, calculating even on Mr Robins's own principles, the force of gunpowder, instead of being 1000 times, must at least be 1308 times greater than the mean pressure of the atmosphere. From this experiment, the Count thought himself warranted in concluding, that the principles affumed by Mr Robins were erroneous, and that his mode of accertaining the force of gunpowder could never fatisfactorily determine it. Despairing of success in that way, he resolved to make an attempt for afcertaining this force by actual meafurement; and after many unfuccessful experiments, he was at length led to conclude, that this force was at least 50,000 times greater than the mean pressure of the atmosphere.

Mr Robins apprehends that the force of fired gunpowder confifts in the action of a permanently elastic fluid, fimilar in many respects to common atmospherical air; and this opinion has been very generally received: but Count Rumford thinks, that though the permanently elaftic fluids, generated in the combustion of gunpowder, affift in producing the effects which refult from its explosion, its enormous force, allowing it to be 50,000 times greater than the mean pressure of the atmosphere, cannot be explained, without supposing that it arises principally from the elasticity of the aqueous vapour generated from the powder in its com-

bustion.

"The brilliant discoveries of modern chemists (says he) have taught us, that both the conflitment parts of which water is composed, and even water itself, exist in the materials which are combined to make gunpowder; and there is much reason to believe that water is actually formed, as well as ditengaged, in its combustion. M. Lavoisier, I know, imagined that the force of fired gunpowder depends in a great measure upon the expansive force of uncombined caloric, supposed to be let loose in great abundance during the combustion or deflagration of the powder: but it is not only dangerous to admit the action of an agent whose existence is not yet clearly demonstrated; but it appears to me that this supposition is quite unnecessary, the elastic force of the heated aqueous vapour, whose existence can hardly be doubted, being quite sufficient to account for all the phænomena. It is well known that the elasticity of aqueous vapour is incomparably more augmented by any given augmentation of temperature than that of any permanently elastic fluid whatever; and those who are acquainted with the amazing force of steam, when heated only to a few degrees above the boiling point, can eafily perceive that its elafticity must be almost infinite when greatly condensed and heated to the

temperature

w- temperature of red-hot iron; and this heat it must cer- known strength of iron, and the area of the fracture of Gunpowtainly acquire in the explosion of gunpowder. But if the force of fired gunpowder arises principally from the clastic force of heated aqueous vapour, a cannon is nothing more than a fleam engine upon a peculiar con-Aruction; and upon determining the ratio of the elafticity of this vapour to its density, and to its temperature, a law will be found to obtain very different from that assumed by Mr Robins in his Treatise on Gun-

In order to measure the elastic force of fired gunpowder, Count Rumford adopted a new plan; and, inflead of causing the generated elastic sluid to act on a moveable body through a determined space, which he .had found to be ineffectual to his purpose, he contrived an apparatus in which this fluid should be made to act, " by a determined furface, against a weight, which, by being increased at pleasure, should at last be such as would just be able to confine it, and which in that case would just counterbalance and consequently measure the

elastic force."

Having succeeded in setting fire to the powder, without any communication with the external air, "by causing the heat employed for that purpose to pass through the folid substance of the barrel, it only remained to apply such a weight to an opening made in the barrel, as the whole force of the generated elastic fluid should not be able to lift, or displace." Many precautions were necessary. A folid block of very hard stone, four feet four inches fquare, was placed upon a bed of folid mafonry, which descended fix feet below the surface of the earth. Upon this block of stone, which ferved as a base to the whole machinery, was placed the small barrel, in which the explosions were made, with its opening directly upwards. This opening was closed by a folid hemisphere of hardened steel, on which the weight to be overcome by the explosion was laid. Having charged the barrel with 10 grains of powder, its whole contents being about 28 grains, and a 24 pounder, weighing 8081 lbs. avoirdupois, being placed on its cascabel so as by its weight to confine the generated elastic fluid, a heated iron ball was applied to the end of the vent tube, (a fmall folid projection from the centre of the bottom of the barrel). In a few moments the powder took fire, though the explosion made a very feeble report; and when the weight was raifed, the confined elaftic vapour rushed out of the barrel. The flight effect produced by this explosion induced some of the attendants on this occafion to undervalue the importance of this experiment, and to form a very inadequate idea of the real force of the elastic sluid that had been thus almost infenfibly discharged. In a second experiment, the barrel was filled with powder, and the same weight laid on as before. The barrel was made of the best hammered iron, and uncommonly strong. The charge of powder amounted to little more than To of a cubic ineh, which is not fo much as would be required to load a fmall pocket pistol, and not one-tenth part of the quantity frequently used for the charge of a common musket. Yet this inconsiderable quantity of powder, when fet on fire, exploded with a force that burst the barrel, and with a loud report that alarmed the whole neighbourhood.

The author proceeds to make an estimate, from the

the barrel in the preceding experiment, of the real force employed by the elaftic vapour to built it; and he computes that it must have been equal to the preffure of a weight of 412529 lbs.; which, by another computation, he found to be 55004 times greater than the mean pressure of the atmosphere. By another process, he investigates the strength of the iron of which the barrel was made; and he thence finds that the force required to built it was equal to the pressure of a weight of 4106241 lbs. This weight, reduced into atmospheres, gives 54750 atmospheres for the meafure of the force exerted by the elastic sluid in the prefent instance. This force must be considerably less than the initial force of the elastic fluid generated in the combustion of gunpowder, before it has begun to expand; "for it is more than probable (fays Count Rumford) that the barrel was in fact burst before the generated elastic sluid had exerted all its force, or that this fluid would have been able to have burth a barrel still stronger than that used in the experiment."

After having shewn the extreme force of fired gunpowder, the Count adverts to an objection which may be made against his deductions. How does it happen that fire-arms and artillery of all kinds, which certainly are not calculated to withstand so enormous a force, are not always burlt when they are used? Instead of answering this question, by asking how it happened that the extremely strong barrel used in his experiment could be burt by the force of gunpowder, if this force be not in fact much greater than it has ever been supposed to be, he proceeds to shew that the combustion of gunpowder, inflead of being inflantaneous, as Mr Robins's theory supposes, is much less rapid than has hitherto been apprehended; an observation, which, if established, is certainly sufficient to answer the objection.

He remarks, that it is a well-known fact, that on the discharge of sire arms of all kinds there is always a confiderable quantity of unconfirmed grains of gunpowder blown out of them; and what is very remarkable, as it leads directly to a discovery of the cause of this effect, these unconsumed grains are not merely blown out of the muzzles of fire-arms, but come out also by their vents or touch-holes, where the fire enters to inflame the charge, as many persons who have had the misfortune to fland with their faces near the touch-hole of a musket, when it has been discharged, have found to their

It appears extremely improbable to our author, if not absolutely impossible, that a grain of gunpowder actually in the chamber of the piece, and completely furrounded by flame, should, by the action of that very flame, be blown out of it without being at the same time set on fire. And, if this be true, he considers it as a most decisive proof, not only that the combustion of gunpowder is less rapid than it has generally been thought to be, but that a grain of gunpowder actually on fire, and burning with the utmost violence over the whole of its surface, may be projected with such a velocity into a cold atmosphere, as to extinguish the fire, and fuffer the remains of the grain to fall to the ground unchanged, and as inflammable as before.

This extraordinary fact was afcertained beyond all possibility of doubt by the Count's experiments. Ha. ving procured from a powdermill in the neighbourhood

Gunpow- of the city of Munich a quantity of gunpowder, all of the same mass, but formed into grains of very different fizes, forze as small as the grains of the finest Battel powder, he placed a number of vertical screens of very thin paper, one behind another, at the distance of 12 inches from each other; and loading a common musket repeatedly with this powder, fometimes without and fometimes with a wad, he fired it against the foremost screen, and observed the quantity and effects of the unconfumed grains of powder which impinged against it. The screens were so contrived, by means of double frames united by hinges, that the paper could be changed with very little trouble, and it was actually changed after every experiment.

The distance from the muzzle of the gun to the first screen was not always the same; in some of the experiments it was only 8 feet, in others it was 10, and in

some 12 feet.

The charge of powder was varied in a great number of different ways; but the most interesting experiments were made with one fingle large grain of powder, propelled by fmaller and larger charges of very fine grained

These large grains never failed to reach the screen: and though they sometimes appeared to have been broken into several pieces by the force of the explosion, yet they frequently reached the screen entire; and fometimes passed through all the screens (five in num-

ber) without being broken.

When they were propelled by large charges, and confequently with great velocity, they were feldom on fire when they arrived at the first screen; which was evident, not only from their not fetting fire to the paper (which they sometimes did), but also from their being found sticking in a foft board, against which they struck, after having passed through all the five screens; or leaving visible marks of their having been impinged against it, and being broken to pieces and dispersed by , the blow. These pieces were often found lying on the ground; and from their forms and dimensions, as well as from other appearances, it was often quite evident that the little globe of powder had been on fire, and that its diameter had been diminished by the combustion before the fire was put out, on the globe being projected into the cold atmosphere.

That these globes or large grains of powder were always fet on fire by the combustion of the charge, can hardly be doubted. This certainly happened in many of the experiments; for they arrived at the screens on fire, and let fire to the paper; and in the experiments in which they were projected with small velocities, they were often feen to pass through the air on fire; and when this was the case, no vestige was to be found. They sometimes passed on fire through feveral of the foremost screens without setting them on fire, and let fire to one or more of the hindmost, and then went on and impinged against the board, which was placed at the distance of 12 inches behind

the last fereen.

The Count then proceeds to mention another experiment, in which the progressive combustion of gunpowder was shewn in a manner still more striking and not

A fmall piece of red-hot iron being dropped down into the chamber of a common horse pistol, and the pistol being elevated to an angle of about 45 degrees,

upon dropping down into its barrel one of the small Gunpon globes of powder (of the fize of a pea), it took fire, der. and was projected into the atmosphere by the elastic fluid generated in its own combustion, leaving a very beautiful train of light behind it, and difappearing all at once like a falling flar. This amnling experiment was repeated very often, and with globes of different fizes. When very small ones were used fingly, they were commonly confumed entirely before they came out of the barrel of the pistol; but when feveral of them were used together, some, if not all of them, were commonly projected into the atmosphere on fire.

As the flowness of the combustion of gunpowder is undoubtedly the cause which has prevented its enormous and almost incredible force from being discovered, our author deduces, as an evident consequence, that the readiest way to increase its effects, is to contrive matters fo as to accelerate its inflammation and combustion. This may be done in various ways; but, in his opinion, the most simple and most effectual manner of doing it would be to fet fire to the charge of powder, by shooting (through a small opening) the flame of a smaller charge into the midst of it.

He contrived an instrument on this principle for firing cannon three or four years ago; and it was found, on repeated trials, to be useful, convenient in practice, and not liable to accidents. It likewife fuperfedes the necessity of using priming, of vent tubes, port-fires, and matches; and on that account he imagined it might be of use in the British navy, but it does not appear to

have been received into practice.

Another infallible method of increasing very confiderably the effect of gunpowder in fire arms of all forts and dimensions, would be to cause the bullet to fit the bore exactly, or without windage, in that part of the bore at least where the bullet rests on the charge; for, when the bullet does not completely close the opening of the chamber, not only much of the elastic fluid, generated in the first moment of the combustion of the charge, escapes by the side of the bullet; but what is of still greater importance, a considerable part of the unconfumed powder is blown out of the chamber along with it in a state of actual combustion, and, getting before the bullet, continues to burn on as it passes through the whole length of the bore; by which the motion of the bullet is much impeded.

The loss of force which arises from this cause, is in fome cases almost incredible; and it is by no means difficult to contrive matters to as to render it very appa-

rent, and also to prevent it.

If a common horse-pistol be fired with a loose ball, and so small a charge of powder that the ball shall not be able to penetrate a deal board fo deep as to stick in it when fired against it from the distance of fix feet; the fame ball, discharged from the same pistol with the fame charge of powder, may be made to pass quite through one deal board, and bury itself in a fecond placed behind it, merely by preventing the loss of force which arises from what is called windage, as he found more than once by actual experiment.

The Count has in his possession a musket, from which, with a common charge of powder, he fires two bullets at once with the same velocity that a single bullet is discharged from a musket on the common con-Aruction with the same quantity of powder. And, what renders the experiment still more striking, the

diameter

Gun w- diameter of the bore of his musket is exactly the same this new powder which was made at Woolwich, and Gunter. as that of a comm n musket, except only in that part of it where it joins the chamber, in which part it is just so much contracted, that the bullet, which is next to the powder, may tlick fast in it. He adds, that though the bullets are of the common fize. and are confequently confiderably less in diameter than the bore, means are used which effectually prevent the loss of force by windage; and to this last circumstance, he concludes, it is doubtless owing, in a great measure, that the charge appears to exert lo great a force in propelling the bullets.

That the conical form of the lower part of the bore where it unites with the chamber has a confiderable share in producing this extraordinary effect, is, however, very certain, as he has found by experiments made

with a view merely to ascertain that fact.

At the close of the Count's last memoir, we have a computation, designed to shew that the force of the elastic sluid generated in the combustion of gunpowder; enormous as it is, may be fatisfactorily explained on the supposition that it depends folely on the elasticity of watery vapour, or steam. From experiments made in France in the year 1790, it appears that the elasticity of steam is doubled by every addition of temperature equal to 30° of Fahrenheit's thermometer. As the heat generated in the combustion of gunpowder cannot be less than that of red hot iron, it may be supposed equal to 1000° of Fahrenheit's scale: -but the elastic force of steam is just equal to the mean pressure of the atmosphere, when its temperature is equal to that of boiling water, or to 212° of Fahrenheit's thermometer; consequently 2120+300=2400 will reprefent the temperature, when its elasticity will be equal to the pressure of two atmospheres; and, pursuing the calculation, at 602°, or 2° above the heat of boiling linfeed oil, its elasticity will be equal to the pressure of 8192 atmospheres, or above eight times greater than the utmost force of the fluid generated in the combuftion of gunpowder, according to Mr Robins's computation: but the heat in this case is much greater than that of 602° of Fahrenheit; and therefore the elasticity of the iteam generated from the water contained in the powder must be much greater than the pressure of 8192 atmospheres. At 722°, the elasticity will be equal to the pressure of 131,072 atmospheres; and this temperature is less than the heat of iron, which is visibly redhot in daylight, by 3550: -- but the flame of gunpowder has been found to melt brass, which requires a heat equal to that of 3807° of Fahrenheit; 2730° above the heat of red hot iron, or 3805" higher than the temperature which gives to fleam an elasticity equal to the pressure of 131,072 atmospheres. That there is in gunpowder water fufficient for supplying the necessary quantity of steam, the author has very fatisfactorily evinced: but we must not pursue his curious investigations any farther. Those who want a fuller account of them, will find it either in the original memoirs themselves, or in a very accurate abridgement of these memoirs in the first volume of Nicholson's Journal of Natural Philosophy, &c.

We cannot conclude this article without mentioning a new kind of gunpowder, invented some years ago in France, in which the marine acid is substituted, in equal quantity, for nitre. Dr Hutton tried some of operating in his own words.

found it of about double the strength of the ordinary fort; but it is not likely to come into common and general use, for the preparation of the acid is difficult and expensive, (See CHEMISTRY-Index in this Suppl.), and the powder which is made of it cauches fire and explodes from the fmallest degree of heat, and without the aid of a spark. It is to this circumstance, however, that its superior strength seems to be in a great meafure owing.

GUNTER's CHAIN. See GEOMETRY, Encyclopæ-

dia, Part II. chap. 1.

GUT-TIE, a dangerous disease to which oxen and male calves are rendered liable by an improper mode of castration. In some places, and particularly in Herefordshire, the breeders of cattle, when they castrate their calves, open the scrotum, take hold of the testicles with their teeth, and tear them out with violence; by which means all the veffels thereto belonging are ruptured. The vafa deferentia, entering by the holes of the transverse and oblique muscles into the abdomen, pass over the ureters in acute angles; at which turning; by their great length and elastic force, the peritoneum is ruptured; the vafa deferentia are severed from the testicles, and springing back, form a kind of bow from the urethra, where they are united, over the ureters, to the transverse and oblique muscles, and there again unite, where they first entered the abdomen; the part of the gut that is tied is the jejunum, at its turning from the left fide to the right, and again from the right to-the left, forming right angles under the kidney, and attached to the duplicature of the peritoneum, to which it was united, where the rupture happened. There the bow of the gut hangs over the bow of the vafa deferentia, which, by a sudden motion, or turn of the beast, form a hitch or tie of the string round the bow of the gut (filled with air), fimilar to what a carter makes on his cart line. This causes a stoppage in the bowels, and brings on a mortification, which, in two days, or four at most, proves fatal: And to this accident is the beaft, when caftrated as above, liable from the day that he was castrated till the time of his being slaughtered.

The fymptoms of the gut tie are the same as those of an incurable colic, volvulus, or mortification of the bowels. The beaft affected with this complaint will kick at its belly, lie down, and groan; it has also a total stoppage in its bowels (except blood and mucus, which it will void in large quantities), and a violent fever, &c. To distinguish with certainty the gut-tie from the colic, &c. the hand and arm of the operator must be oiled; and introduced into the anus, through the rectum, beyond the os pubis, turning the hand down to the transverse and oblique muscles, where the vessels of the testicles enter the abdomen. There the string will be found united to the muscles, and is easily traced to the stricture by the hand, without pain to the beast.

From the general view of the agriculture of the county of Hereford, drawn up by Mr Clark of Builth, Breconshire, we learn that Mr Harris sarmer at Wickton, near Leominster, had been uncommonly successful in the cure of the gut tie. That gentleman informs us, that he had cut cattle for this disease from the age of three months to that of nine years; and as it is a matter of great importance, we shall state his method of

"The only method of cure (fays he) that can be fafely ventured upon is, to make a perpendicular incision, four inches under the third vertebra of the loins, on the left fide, over the paunch or stomach, and introduce the arm to find the part affected; if possible, keep the beaft standing by the help of proper affistants. The knife I make use of to severe the string is in the form of a large fish-hook, with an edge on the concave fide; it is fixed to a ring, which fits the middle finger, which finger crooks round the back of the knife, the end of the thumb being placed on its edge. The infrom wounding the furrounding intestines; with it I divide the string or strings, and bring out one or both, as circumstances require. Here it is to be observed, that great care must be taken by the operator not to wound or divide the ureters, which would be certain death. I then few up the divided lips of the peritoneum very close, with a furgeon's needle threaded with firong thread, eight or ten double, sufficiently waxed; I also sew up the skin, leaving a vacancy at the top and bottom of the wound fufficiently wide to introduce a tent of furgeon's tow, spread with common digestive and traumatic balfam; covering the incision with a plafter made of the whites of eggs and wheat flour. The wound, thus treated, and dressed every day, will be

well in a fortnight. The medicine I give to remove Guttie, the stoppage in the three stomachs occasioned by the tie, and to carry off the fever, is four ounces of Glauber's fait, two ounces of cream of tartar, and one ounce of sena, infused in two pounds of boiling water, adding half a pound of olive-oil, and working it off with plenty of gruel, mixed with a large quantity of infusion of mallows and elder bark. I administer the gruel and infusion for at least two or three days; by which time the beaft will be well, will eat his provender, and chew the cud, and will for ever be relieved, and remain fafe from this fatal disorder.

"The following fimple and easy method of castration will effectually prevent the gut-tie. Open the fcrotum, loofen out the testicles, and tie the several vesfels with a waxed thread or filk; or fear them with a hot iron, to prevent their bleeding, as in the common way of cutting colts. This method can never displace the vessels of the testicles, bladder, kidneys, or intestines; all of which remain covered or attached to the peritoneum, or lining of the abdomen of the beaft, which renders it impossible that there should ever be

a stricture or tie on the gut."

GUZ, an Indian measure, varying in different places. but which may be reckoned about an English yard. The guz of Akbar was 41 fingers.

HANCES, HANCHES, HAUNCHES, or Hanses, in architecture, are certain small intermediate parts of Harriot. arches between the key or crown and the fpring at the bottom, being perhaps about one-third of the arch, and fituated nearer the bottom than the top or crown; and are otherwise called the spandrels. See ARCH in this

> HANSPIKE, or HANDSPEC, a lever or piece of ftrong wood, for raising by the hand great weights, &c. It is five or six feet long, cut thin and crooked at the lower end, that it may get the easier between things that are to be separated, or under any thing that is to be raifed. It is better than a crow of iron, because its

length allows a better poife.

HARRIOT (Thomas) was a very eminent mathematician of the 16th and 17th centuries, of whom some account has been given in the Encyclopedia Britannica. In that article it has been shewn, that Des Cartes had feen some improvements of Harriot's in algebra, and published them to the world as his own; but this piece of plagiarism has been more completely proved in the Astronomical Ephemeris for the year 1788, by Dr Zach, astronomer to the Duke of Saxe-Gotha; who likewise shews that Harriot was an astronomer as well as an algebraift.

46 I here present to the world (says the Doctor) a short account of some valuable and curious manuscripts, which I found in the year 1784 at the feat of the earl

of Egremont, at Petworth in Suffex.

" A predecessor of the family of lord Egremont, Harriott viz. that noble earl of Northumberland, named Henry Percy, was not only a generous favourer of all good learning, but also a patron and Mæcenas of the learned men of his age. Thomas Harriot, the author of the faid manuscripts, Robert Hues (well known by his Treatife upon the Globes), and Walter Warner, all three eminent mathematicians, who were known to the earl, received from him yearly pensions; so that when the earl was committed prisoner to the Tower of London in the year 1606, our author, with Hues and Warner, were his constant companions; and were usually called the earl of Northumberland's three Magi.

"Thomas Flarriot is a known and celebrated mathematician among the learned of all nations, by his excellent work, Artis Analytica Praxis, ad aquationes algebraicas nova expedita & generali methodo, refolvendas, Tractatus posthumus; Lond. 1631: dedicated to Henry earl of Northumberland; published after his death by Walter Warner. It is remarkable, that the fame and the honour of this truly great man were conflantly attacked by the French mathematicians, who could not endure that Harriot should in any way diminish the fame of their Vieta and Des Cartes, especially the latter, who was openly accused of plagiarism from our au-

"Des Cartes published his Geometry six years after Harriot's work appeared, viz. in the year 1637. Sir Charles Cavendish, then ambassador at the French court Philot at Paris, observed to the famous geometrician Roverval, that these improvements in analysis had been already made these fix years in England, and shewed him afterwards Harriot's Artis Analytica Praxis; which, as Roverval was looking over, at every page he cried out, Oui! oui! il l'a vu! Tes! yes! he has feen it! Des Cartes had also been in England before Harriot's death, and had

heard of his new improvements and inventions in analyfis. " Now all this relates to Harriot the celebrated analyst; but it has not hitherto been known that Harriot was an eminent astronomer, both theoretical and practical, which first appears by these manuscripts; among which, the most remarkable are 199 observations of the fun's fpots, with their drawings, calculations, and determinations of the fun's rotation about his axis. There is the greatest probability that Harriot was the first discoverer of these spots, even before either Galileo or Scheiner. The earliest intelligence we have of the first discovered solar spots is of one Joh. Fabricius Phrysius, who in the year 1611 published at Wittemberg a small treatise, intitled, De Maculis in Sole obfervatis & opparente eorum cum Sole conversione narratio. Galileo, who is commonly accounted the first discoverer of the solar spots, published his book, Istoria e Dimonstrazioni intorne alle Machie Solare e loro accidenti, at Rome in the year 1613. His first observation in this work is dated June 2d 1612. Angelo de Filiis, the editor of Galileo's work, who wrote the dedication and preface to it, mentions, page 3. that Galileo had not only discovered these spots in the month of April in the year 1611, at Rome, in the Quirinal Garden, but had thewn them feveral months before (molti mesi innanzi) to his friends in Florence; and that the observations of the difguised Apelles (the Jesuit Scheiner, a pretender to this first discovery) were not later than the month of October in the same year; by which the epoch of this discovery was fixed to the beginning of the year 1611. But a passage in the first letter of Galileo's works, pa. 11. gives a more precise term to this discovery. Galileo there fays in plain terms, that he had observed the spots in the sun 18 months before. The date of this letter is May 24. 1612; which brings the true epoch of this discovery to the month of November 1610. However, Galileo's first produced observations are only from June 2. 1612, and those of father Scheiner of the month of October in the same year. But now it appears from Harriot's manuscripts, that his first observations of these spots are of Dec. 8. 1610. It is not likely that Harriot could have this notice from Galileo, for I do not find this mathematician's name ever quoted in Harriot's papers: But I find him quoting book i. chap. 2. of Joseph a Costa's Natural and Moral History of the West Indies; in which he relates, that in Peru there are spots to be seen in the sun which are not feen in Europe: and hence it is probable, that Flarriot took the hint of looking for fuch fpots. Befides, it is not unlikely, that living with fo munificent a patron, Harriot got from Holland the new invented telescopes much sooner than they could reach Galileo, who at that time lived at Venice. Harriot's very careful and exact observations of these spots, shew also that he was in possession of the best and most improved telescopes of that time; for it appears he had some with magnifying powers of 10, 20, and 30 times. At least there are no earlier observations of the solar SUPPL. VOL. I. Part II.

spots extant than his; they run from December 8. Harriot. 1610, till January 18. 1613. I compared the corresponding ones with these observed by Galileo, between which I found an exact agreement. Had Harriot had any notion about Galileo's discoveries, he certainly would have also known something about the phases of Venus and Mercury, and especially about the fingular shape of Saturn, first discovered by Galileo; but I find not a word in all his papers concerning the particular figure of that planet.

"I found likewise (continues Dr Zach) among the papers of Harriot a large fet of observations on the satellites of Jupiter, with drawings of them, their positions, and calculations of their revolutions and periods. His first observation of those discovered satellites. I find to be of January 16. 1610; and they go till February 26. 1612. Galileo pretends to have discovered them January 7. 1610; fo that it is not improbable that Harriot was likewise the first discoverer of these attend-

ants of Jupiter.

"Among his other observations of the moon, of eclipses, of the planet Mars, of folfices, of refraction, of the declination of the needle, &c. there are remarkable ones of the comet of 1607, and the latter comet (for there were two) of 1618. They were all observed with a crofs-staff, by measuring their distances from fixed stars; whence these observations are the more valuable, as comets had before been but grofsly observed. Kepler himself observed the comet of 1607 only with the naked eye, pointing out its place by a coarse estimation, without the aid of an instrument; and the elements of their orbits could, in defect of better observations, be only calculated by them. The observations of the comet of the year 1607 are of the more importance, even now for modern aftronomy, as this is the same comet that fulfilled Dr Halley's prediction of its return in the year 1759 That prediction was only grounded upon the elements afforded him by these coarie observations; for which reason he only assigned the term of its return to the space of a year. The very intricate calculations of the perturbations of this comet, afterwards made by M. Clairaut, reduced the limits to a month's space. But a greater light may now be thrown upon this matter by the more accurate observations on this comet by Mr Harriot. In the month of October 1785, when I conversed upon the subject of Harriot's papers, and especially on this comet, with the celebrated mathematician M. de la Grange, director of the Royal Academy of Sciences at Berlin, he then fuggested to me an idea, which, if brought into execution, will clear up an important point in attronomy. It is well known to aftronomers how difficult a matter it is to determine the mass, or quantity of matter, in the planet Saturn; and how little fatisfactory the notions of it are that have hitherto been formed. The whole theory of the perturbations of comets depending upon this uncertain datum, feveral attempts and trials have been made towards a more exact determination of it by the most eminent geometricians of this age, and particularly by la Grange himfelf; but never having been fatisfied with the few and uncertain data heretofore obtained for the resolution of this problem, he thought that Harriot's observations on the comet of 1607, and the modern ones of the same comet in 1759, would suggest a way of resolving the problem à posteriori; that of determining

Hasselquist by them the elements of its ellipsis. The retardation of the comet compared to its period, may clearly be laid to the account of the attraction and perturbation it has suffered in the region of Jupiter and Saturn; and as the part of it belonging to Jupiter is very well known, the remainder must be the share which is due to Saturn; whence the mass of the latter may be inferred. In consequence of this consideration, I have already begun to reduce most of Harriot's observations of this comet, in order to calculate by them the true elements of its orbit on an elliptical hypothsis, to complete M. de la Grange's idea upon this matter.

"I forbear to mention here any more of Harriot's analytical papers, which I found in a very great number. They contain feveral elegant folutions of quadratic, cubic, and biquadratic equations; with some other folutions and loca geometrica, that shew his eminent qualifications, and will ferve to vindicate them against the attacks of feveral French writers, who refuse him the justice due to his skill and accomplishments, merely to fave Des Cartes's honour, who yet, by fome impartial men of his own nation, was accused of public

plagiarifm."

HASSELOUIST (Frederick) was born in the province of East Gothland in 1722, and studied medicine and botany in the university of Upsal. Linnæus had in his lectures reprefented the extraordinary merits and great celebrity which a young student might obtain by travelling through Palestine, and by inquiring into and describing the natural history of that country, which was till then unknown, and had become of the greatest importance to interpret the bible, and to understand eastern philology. Hasselquist was fired with ambition to accomplish an object so important in itself, and fo warmly recommended by his beloved mafter. There being no fund arifing from the liberality of the crown, private collections were made, which poured in very copioufly, especially from the native country of the young traveller. All the faculties of the university of Upfal also granted him a stipend.

Thus protected, he commenced his journey in the fummer of 1749. By the interference of Lagerstroem, he had a free passage to Smyrna in one of the Swedish East Indiamen. He arrived there at the conclusion of the year, and was received in the most friendly manner by Mr A. Rydel, the Swedish consul. In the beginning of 1750 he fet out for Egypt, and remained nine mouths at Cairo the capital. Hence he fent to Linnæus, and to the learned focieties of his country, fome specimens of his researches. They were published in the public papers, and met with the greatest approbation; and upon the proposition of Dean Baeck and Dr Wargentin, fecretary of the Royal Academy of Sciences, a collection of upwards of 10,000 dollars in copper money was made for the continuance of the travels of young Hasselquist. Counsellors Lagerstroem and Nordencrantz were the most active in railing subscriptions at Stockholm and Gothenburgh. In the spring of 1751, he repaired to his destination, and passed through Jaffa to Jerusalem, Jericho, &c. He returned afterwards through Rhodus and Scio to Smyrna. Thus he fulfilled all the expectations of his country, but he was not to reap the reward of his toils. The burning heat

of the fandy deferts of Arabia had affected his lungs; Hu. he reached Smyrna in a state of illness, in which he languished for some time, and died February 9. 1752,

in the 30th year of his age.

The fruits of his travels were, however, preserved through the liberality of a great princess. He had been obliged to contract debts. The Turks, therefore, feized upon all his collections, and threatened to expose them to public fale. The Swedish conful prevented it. He fent, with the intelligence of the unhappy exit of his countryman, an account of the distresses under which he died; - and at the representation of Dean Baeck, Queen Louisa Ulrica granted the sum of 14,000 dollars in copper specie to redeem all his collections. They arrived afterwards in good prefervation at Stockholm; confisting of a great quantity of antiques, Arabian manuscripts, shells, birds, serpents, insects, &c. and were kept in the cabinets at Ulrichfdale and Drottningholm. The specimens of the natural curiofities of these museums being double or treble in number, Linnæus obtained some of them, and published the voyage of his ill-fated friend, and honoured his memory with a plant, which he called from his name Haffelquistia. HASSEL-QUISTA, Encycl.

HAT MAKING is a mechanical process, which is detailed in the Encyclopadia from the best information that could then be obtained. We have lately learned, however, that our detail is fometimes defective, and fometimes erroneous; and it is our duty to fupply those defects, and to correct those errors. But, strangers as we are to the business of hat-making, we should not perhaps have fuspected, that we had been misled by the perfons whom we confulted, had we not been informed by a very intelligent writer in Nicholfon's Philosophical Journal, that the account of the manufacturing of hats, which is given in the Encyclopadia is far from the truth. This information induced us to look through the Journal itself for a more accurate account of the process; well convinced, that the liberal-minded author of that work would not have pointed out our mistakes without making us welcome to avail ourselves of his aid to correct them. Our readers will therefore be indebted only to Mr Nicholfon and his correspondent for whatever instruction they may derive from this article; and as we wish not to deck ourselves in borrowed plumes, we shall communicate that instruction in the words of its author.

Having visited the manufactory of Messrs Collinsons, hatters in Gravel-lane, Southwark, Mr Nicholfon gives

the following account of their procedure:

"The materials for making hats are rabbits fur cut off from the skin, after the hairs have been plucked out, together with wool and beaver. The two former are mixed in various proportions, and of different qualities, according to the value of the article intended to be made; and the latter our author believes to be univerfally used for facing the finer articles, and never for the body or main stuff. Experience has shewn, that these materials cannot be evenly, and well felted together, unless all the fibres be first separated, or put into the same state with regard to each other. This is the object of the first process, called bowing. The material, without any previous preparation (A), is laid upon a platform of wood,

⁽A) Some writers mention a partial wetting of the fur while on the skin, by lightly smearing it with a solution of nitrate of mercury to give it a curl. Messrs Collinsons do not use it, nor any other preparation.

or of wire, somewhat more than four feet square, called a burdle, which is fixed against the wall of the work-shop, and is enlightened by a small window, and separated by two side partitions from other hurdles, which occupy the rest of the space along the wall. The hurdle, if of wood, is made of deal planks, not quite three inches wide, disposed parallel to the wall, and at the distance of one-fortieth or one-fistieth of an inch from each other, for the purpose of suffering the dust, and other impurities of the stuff, to pass through; a purpose still more effectually answered by the hurdle of wire.

"The workman is provided with a bow, a bow pin, a basket, and several cloths. The bow is a pole of yellow deal wood, between seven and eight feet long, to which are fixed two bridges, fomewhat like that which receives the hair in the bow of the violin (B). Over these is stretched a catgut, about one-twelfth part of an inch in thickness. The bow-pin is a stick with a knob, and is used for plucking the bow-string. The basket is a square piece of ozier work, consisting of open strait bars with no croffing or interweaving. Its length across the bars may be about two feet, and its breadth eighteen inches. The fides into which the bars are fixed are flightly bended into a circular curve, fo that the basket may be set upright on one of these edges near the right hand end of the hurdle, where it usually stands. The cloths are linen. Besides these implements, the workman is also provided with brown paper.

"The bowing commences by shovelling the material towards the right hand partition with the basket, upon which, the workman holding the bow horizontally in his left hand, and the bow-pin in his right, lightly places the bow-string, and gives it a pluck with the pin. The string, in its return, strikes part of the fur, and causes it to rise, and sty partly across the hurdle in a light open form. By repeated strokes, the whole is thus subjected to the bow; and this beating is repeated till all the original clots or masses of the silaments are perfectly opened and obliterated. The quantity thus treated at once is called a batt, and never exceeds half the

quantity required to make one hat.

"When the batt is sufficiently bowed, it is ready for hardening; which term denotes the first commencement of felting. The prepared material being evenly difpofed on the hurdle, is first pressed down by the convex fide of the basket, then covered with a cloth, and pressed fucceffively in its various parts by the hands of the workman. The preffure is gentle, and the hands are very flightly moved back and forwards at the same time through a space of perhaps a quarter of an inch, to favour the hardening or entangling of the fibres (See FELTING in this Suppl.) In a very short time, indeed, the stust acquires sufficient sirmness to bear careful handling. The cloth is then taken off, and a fneet of paper, with its corners doubled in, so as to give it a triangular outline, is laid upon the batt, which last is folded over the paper as it lies, and its edges, meeting one over the other, form a conical cap. The joining is foon made good by preffure with the hands on the cloth. Another batt, ready hardened, is in the next place laid on the hurdle, and the cap here mentioned placed upon it, with the joining downwards. This last batt being alfo folded up, will confequently have its place of junction diametrically opposite to that of the inner felt, which it must therefore greatly tend to strengthen. The principal part of the hat is thus put together, and now requires to be worked with the hands a confiderable time upon the hurdle, the cloth being also occasionally sprinkled with clear water. During the whole of this operation, which is called basoning (c), the article becomes firmer and firmer, and contracts in its dimensions. It may easily be understood, that the chief use of the paper is to prevent the fides from felting together.

"The basoning is followed by a still more effectual continuation of the selting, called working (n). This is done in another shop, at an apparatus called a battery, consisting of a kettle (containing water slightly acidulated with sulphuric acid, to which, for beaver hats, a quantity of the grounds of beer is added, or else plain water for rinsing out), and eight planks of wood joined together in the form of a frustum of a pyramid, and meeting in the kettle at the middle. The outer or upper edge of each plank is about two feet broad, and

4 Z 2 rif

(B) Mr Nicholfon's correspondent, who is himself a hatter, says that the bow is best made of ash; that it is composed of the stang or handle; that the bridge at the smaller end, or that which is nearest the window in the act of bowing, is called the cock; and that the other bridge, which is nearer to the workman's hand, is called the breech.

may be in part discovered; but in part only.

(D) The intelligent writer, who has been so often quoted, says, that before this operation is begun, the hat is dipped into the boiling kettle, and allowed to lie upon the plank until cold again; this is called foaking, that is, being perfectly saturated with the hot liquor: if they are put in too hashily in this state, for they are then only bowed and basoned, they would burst from the edges, each batt not being sufficiently selted into the other.

⁽c) Mr Nicholson's correspondent says, that after bowing, and previous to the basoning, a hardening skin, that is, a large piece of skin, about four feet long and three feet broad, of leather alumed or half tanned, is pressed upon the bat, to bring it by an easier gradation to a compact appearance; after which it is basoned, being still kept upon the hurdle. This operation, the basoning, derives its name from the process or mode of working, being the same as that practised upon a wool hat after bowing; the last being done upon a piece of cast metal, four feet across, of a circular shape, called a bason: the joining of each batt is made good here by shuffling the hand, that is, by rubbing the edges of each batt folded over the other to excite the progressive motion of each of the silaments in felting, and to join the two together. Many journeymen, to hurry this work, use a quantity of vitriol (sulphuric acid), and then, to make the nap rise and flow, they kill the vitriol, and open the body again by throwing in a handful or two of oatmeal; by this means they get a great many made, though, at the same time, they leave them quite grainy from the want of labour. This, in handling the dry grey hat when made may be in part discovered; but in part only.

rifes a little more than two feet and a half above the ground; and the slope towards the kettle is confiderably rapid, so that the whole battery is little more than fix feet in diameter. The quantity of fulphuric acid added to the liquor is not fufficient to give a four tafte, but only renders it rough to the tongue. In this liquor, heated rather higher than unpractifed hands could bear, the article is dipped from time to time, and then worked on the planks with a roller, and also by folding or rolling it up, and opening it again; in all which, a certain degree of care is at first necessary, to prevent the fides from felting together; of which, in the more advanced stages of the operation, there is no danger. The imperfections of the work now present themselves to the eye of the workman, who picks out knots and other hard substances with a bodkin, and adds more felt upon all fuch parts as require strengthening. added felt is patted down with a wet brush, and soon incorporates with the rest. The beaver is laid on towards the conclusion of this kind of working. Mr Nicholfon could not diffinctly learn why the beer grounds were used with beaver-hats. Some workmen faid, that by rendering the liquor more tenacious, the hat was enabled to hold a greater quantity of it for a longer time; but others faid, that the mere acid and water would not adhere to the beaver facing, but would roll off immediately when the article was laid on the plank. It is probable, as he observes, that the manu. facturers who now follow the established practice, may not have tried what are the inconveniences this addition is calculated to remove."

Our author's correspondent, however, assigns several reasons for the addition of those dregs, which, he says, ought to be thick, and the fourest that can be got. 1. Vitriol (sulphuric acid) would harden the hat too much, which is kept mellow by the dregs. 2. The dregs are said by the workmen to hold or fill the body, whilft a little vitriol cleanfes it of the dirt, &c. that may be on the rabbit or other wools. 3. Another advantage attending the use of dregs, whether of beer, porter, or wine, is, that as the boiling of the dyeing does not draw out much of the mucilage from each hat when it comes to be stiffened, the dregs form a body within the hat, fufficiently strong or retentive to keep the glue from coming through amongst the nap. 4. Vitriol (fulphuric acid) alone purges or weakens the goods too much; consequently half of the quantity does better with the addition of dregs, as it allows the body to be made closer by more work.

Of these four reasons for the use of dregs, the last alone appears to us perspicuous or at all satisfactory. But be this as it may, acid of some kind gives a roughness to the surface of the hair, which facilitates the mechanical action of selting; and Mr Collinson informed Mr Nicholson, that in a process, called carotting, they make use of nitrous acid. In this operation, the material is put into a mixture of the nitrous and sulphuric acids in water, and kept in the digesting heat of a stove all night; by which means the hair acquires a ruddy or yellow colour, and loses part of its strength.

"It must be remembered, that our hat still possesses the form of a cone, and that the whole of the several actions it has undergone have only converted it into a soft slexible felt, capable of being extended, though with some difficulty, in every direction. The next thing to

be done is to give it the form required by the wearer. Hati For this purpose, the workman turns up the edge or rim to the depth of about an inch and a half, and then returns the point back again through the centre or axis of the cap, fo far as not to take out this fold, but to produce another inner fold of the same depth. The point being returned back again in the fame manner, produces a third fold; and thus the workman proceeds, until the whole has acquired the appearance of a flat circular piece, confishing of a number of concentric undulations or folds, with the point in the centre. This is laid upon the plank, where the workman, keeping the piece wet with the liquor, pulls out the point with his fingers, and presses it down with his hand, at the fame time turning it round on its centre in contact with the plank, till he has, by this means, rubbed out a flat portion equal to the intended crown of the hat. In the next place, he takes a block, to the crown of which he applies the flat central portion of the felt, and by forcing a ftring down the fices of the block, he caufes the next part to assume the figure of the crown, which he continues to wet and work, until it has properly difposed itself round the block. The rim now appears like a flounced or puckered appendage round the edge of the crown; but the block being fet upright on the plank, the requisite figure is foon given by working, rubbing, and extending this part. Water only is used in this operation of fashioning or blocking; at the conclusion of which it is pressed out by the blunt edge of a copper implement for that purpose.

"Previous to the dyeing, the nap of the hat is raised or loosened out with a wire brush, or carding instrument. The fibres are too rotten after the dyeing to bear this operation. The dyeing materials are logwood, and a mixture of the sulphates of iron and of copper, known in the market by the names of green copperas and blue vitriol. As the time of Mr Collinson was limited, and my attention, says Mr Nicholson, was more particularly directed to the mechanical processes. I did not go into the dye-house; but I have no doubt that the hats are boiled with the logwood, and afterwards immersed in the faline solution. I particularly asked whether galls were used, and was answered in the negative.

"The dyed hats are, in the next place, taken to the stiffening shop. One workman, assisted by a boy, does this part of the business. He has two vessels, or boilers, the one containing the grounds of strong beer, which costs seven shillings per barrel, and the other vesfel containing melted glue, a little thinner than it is used by carpenters. Our author particularly asked, whether this last folution contained any other ingredient besides glue, and was assured that it did not. The beer grounds are applied in the infide of the crown to prevent the glue from coming through to the face, and also, as he supposes, to give the requisite firmness at a less expence than could be produced by glue alone. If the glue were to pass through the hat in different places, it might, he imagines, be more difficult to produce an even gloss upon the face in the subsequent finishing, The glue stiffening is applied after the beer grounds are dried, and then only upon the lower face of the flap, and the infide of the crown. For this purpose, the hat is put into another hat, called a stiffening hat, the crown of which is notched, or slit open in various directions. These are then placed in a hole in a deal

board, which supports the slap, and the glue is applied with a brush.

" The dry hat, after this operation, is very rigid, and its figure irregular. The last dressing is given by the application of moilture and heat, and the use of the brush, and a hot iron, fomewhat in the shape of that used by tailors, but shorter and broader on the face. The list being foftened by exposure to steam, is drawn upon a block, to which it is fecurely applied by the former method of forcing a string down from the crown to the commencement of the rim. The judgment of the workman is employed in moistening, brushing, and ironing the hat, in order to give and preferve the proper figure. When the rim of the hat is not intended to be of an equal width throughout, it is cut by means of a wooden, or perhaps metallic pattern; but as no fuch hats are now in fashion, Mr Nicholfon faw only the tool for cutting them round. The contrivance is very ingenious and fimple. A number of notches are made in one edge of a flat piece of wood for the purpose of inferting the point of a knife, and from one fide or edge of this piece of wood there proceeds a strait handle, which lies parallel to the notched fide, forming an angle fomewhat like that of a carpenter's fquare. When the legs of this angle are applied to the outlide of the crown, and the board lies flat on the rim of the hat, the notched edge will lie nearly in the direction of the radius, or line pointing to the centre of the hat. A knife being therefore inferted in one of the notches, it is easy to draw it round by leaning the tool against the crown, and it will cut the border very regular and true. This cut is made before the hat is quite finished, and is not carried entirely through; fo that one of the last operations consists in tearing off the redundant part, which by that means leaves an edging of beaver round the external face of the flap. When the hat is completely finished, the crown is tied up in gauze paper, which is neatly ironed down. It is then ready for the fubfequent operations of lining," &c.

Our author concludes his valuable memoir on the fabrication of hats, with some observations on the probable gain or lofs of employing machinery in the manufacture. These observations, as they are stated in the original paper, we recommend to the ferious attention of every judicious hat maker, who carries on his business on a large scale; for he will find them not the reveries of a rash speculatist, but the cool reslections of a real philosopher, who is at the same time no stranger to the arts of life. They fuggest the following subjects of enquiry; Whether carding, which is rapidly and mechanically done, be inferior to bowing, which does not promife much facility for mechanical operation? Whether a fuccession of batts or cardings might be thrown round a fluted cone, which rapidly revolving, in contact with three or more cylinders, might perform the hardening, and even the working, with much more precision and speed than they are now done by hand? Whether blocking or shaping be not an operation extremely well calculated for the operation of one or more machines? Whether loofe weaving and fubfequent felting might not produce a lighter, cheaper, and stronger article? And how far the mechanical felting, which is not confined merely to the hairs of animals, might be applied to this art?

Before we dismiss this subject, it may be worth while

to state Mr Dunnage's method of making water-proof Hat. bats, in imitation of beaver, for which, in November 1794, he obtained a patent. It is as follows: Let a shag be woven, of such count in the reed, and cut over fuch fized wire, as will give the hats to be manufactured from it that degree of richnels, or appearance of fur, which may be thought necessary. The materials of which this shag may be composed are various, and should be accommodated to different kinds of hats, according to the degree of beauty and durability to be given them, and the price at which they are defigned to be fold; that is to fay, filk, mohair, or any other hair that is capable of being foun into an end fine enough for the purpose, cotton, inkle, wool, or a mixture of any, or all the above materials, as may fuit the different purposes of the manufacturer. Those auswer best, (fays our author), which are made with two poles, either of Bergam, Piedmont, or Organzine filk, rifing alternately, in a reed of about nine hundred count to eighteen inches wide, with three shoots over each wire. This method of weaving distributes the filk (as it may be put fingle into the harness), and prevents any ribby appearance which it might have if the filk were passed double, and the whole of the pole cut over each wire. This may be made either on a two or four thread ground of hard filk, shot with fine cotton, which he thinks preferable for shoot, to silk, inkle, or any other material, as it forms both a close and fine. texture. An inferior kind of hats may be made from any of the before mentioned materials, and with cheaper filk. This shag should be stretched on a frame, fuch as dyers use to rack cloth; then (having previoully fet the pile upright with a comb, to prevent its being injured or stuck together), go over the ground with thin fize, laid on with a fost brush. For black, or dark colours, common fize will do; with white, or any light colour, use isinglass, or a size made from white kid leather. These, or gum, or any other muc laginous matter, which, without altering the colour, will prevent oil from getting through the ground fo as to. injure the pile, will answer the purpose. Take care not to apply more of any material, as a preparation, than may be fully faturated with oil or varnish, so that water will not discharge it from the ground. 'The fize, or other glutinous matter, being dry, the pile must be teaseled, or carded with a fine card, till the filk is completely taken out of the twift or throwing, when it will lose its coarse shaggy look, and asfume the appearance of a very fine fur. It must now be once more fet upright with a comb, and you may proceed to lay on your water-proof material; this too. may be varied according to circumstances. For black, or any dark colour, linfeed oil well boiled with the ufual driers, and thickened with a fmall quantity of any good drying colour, will do; for white, or very fine colours, poppy or nut oil, or copal or other varnishes, may be used. In this particular the manufacturer must judge what will best answer his purpose, taking care never to use any thing that will dry hard, or be subject to crack. Mr Dunnage has found good drying linfeed oil preferable to any other thing which he has used, and, with the precaution of laying on very little the first time, it will not injure the finest colours. When the first coat of oil is dry, go over it a second and a third time, if necessary, till you are convinced the.

E11-

pores of the ground are fully closed up, and the stuff rendered impervious to water. It should now stand feveral days, till the fmell is fufficiently gone off; and before it is taken from the frame, should be gone over with fome ox gall or lime-water, to take off the greatinels, which would otherwife prevent the sliffening from adhering to the oil. The material being now ready to be formed into hats, should be cut into proper shapes for that purpose. The crown should be made up over a block, with needle and filk, the oiled fide outwards. The scams should then be rubbed with a piece of hard . wood, bone, or ivory, to make them lie flat, and the edges of the stuff pared off very near the stitches, that no joint may appear on the right side. The seams fhould then be carefully gone over with the prepared oil, till every crevice or hole made by the needle is completely filled up, and the crown rendered perfectly water proof. The crown may then be turned and stiffened, by flicking linen, leather, paper, or any other material that may be found to answer the purpose, to the inner or painted fide, till it aequires about the same degree of fliffness, or resistance to the touch, as a good beaver. The mucilaginous matter which he used to attach the stiffening to the crown, and the upper and funder parts of the brim to each other, was composed of one pound of gum-arabic or fenega, one pound of starch, and a half a pound of glue, boiled up with as much water as reduced the whole to the confistence of a thick paste. A greater or less proportion of any of .these ingredients may be used, and other glutinous and adhesive substances may answer the same purposes; or drying oils may be made use of, instead of this or other mueilage; or any of the refinous gums diffolved in oil or spirits; only it should be observed, in this case, the hats will require more time in the preparation, as the oily matter, unless exposed to the air, will not readily dry; but he found by experience that the above mentioned composition does not dry hard or brittle, but retains that pleasant flexibility which is agreeable to the touch, while it communicates to the other materials a sufficient degree of elasticity. Before the brim is perfectly dry, care should be taken to form a neck or rifing round the hole where it is to be attached to the erown, by notching it round with a pair of sciffars, and then forcing it over a block fomething larger than you have made the hole, fo that the uncut stuff may turn up, under the lower edge of the crown, about a quarter of an inch. Before you join the crown and brim together, go over the outfide of the neek of the brim, and the infide of the crown, as high as the neck will come (which should be about half an inch), with the prepared oil; and when they are nearly dry, so as to adhere to the finger on touching them, put the crown over the neck of the brim, and let them be fewed ftrongly together, taking eare to few down as little of the pile as possible, and using the same precaution of oiling, where the needle has been through, as was observed in making up the erown. The hat is now ready for dreffing; which operation may be performed over a block, with a hot iron, brush, &c. in the same manner as those commonly called felts. When putting in the lining, be very careful to let the needle only take hold of the under furface of the brim; for should it perforate the upper one, the water will find its way through, and the hat be of no value. Though we

have already declared how little we are acquainted with Hawking the operation of hat making, we cannot help fuggefting the enquiry, whether these water-proof hats might not be improved both in strength and beauty, by a slight felting before the application of the fize by the brush. Such of them as are composed of wool or hair, or contain a mixture of these materials, are unquestionably susceptible of felting.

HAWKINS (Sir John), was the youngest fon of a man who, though descended from Sir John Hawkins the memorable admiral and treasurer of the navy in the reign of Queen Elizabeth, followed at first the occupation of a house-earpenter, which he afterwards exchanged for the profession of a surveyor and builder. He was born in the city of London on the 30th day of March 1719; and after having been fent first to one school, and afterwards to a fecond, where he acquired a tolerable knowledge of Latin, he went through a regular course of architecture and perspective, in order to fit him for his father's profession of a surveyor. He was, however, perfuaded, by a near relation, to abandon the profession of his first choice, and to embrace that of the law; and was accordingly articled to Mr John Scott an attorney and folicitor in great practice. In this fitua-tion his time was too fully employed in the actual difpatch of business to permit him, without some extraordinary means, to acquire the necessary knowledge of his profession by reading and study; besides that, his master is said to have been more anxious to render him a good eopying clerk, by ferupulous attention to his hand-writing, than to qualify him by instruction to conduct business. To remedy this inconvenience, therefore, he abridged himself of his rest, and rising at four in the morning, found opportunity of reading all the necessary and most eminent law writers, and the works of our most eelebrated authors on the subjects of verse and profe. By these means, before the expiration of his clerkship, he had rendered himself a very able lawyer, and had acquired a love for literature in general, but particularly for poetry and the polite aits; and the better to facilitate his improvement, he occasionally furnished to the Universal Spectator, the Westminster Journal, the Gentleman's Magazine, and other periodical publications of the time, effays and disquisitions on several subjects. The first of these is believed to have been an Essay on Swearing; but the exact time of its appearance, and the paper in which it was inserted, are both unknown. It was, however, re-published some years before his death (without his knowledge till he faw it in print) in one of the newspapers. His next production was an Essay on Honesty, inserted in the Gentleman's Magazine for March 1739; and which occasioned a controversy, continued through the Magazines for several fuceeeding months, between him and a Mr Calamy, a descendant of the eelebrated Dr Edmund Calamy, then a fellow-elerk with him.

About the year 1741, a club having been inflituted by several amateurs of music, under the name of the Madrigal Society, to meet every Wednesday evening, and his clerkship being now out, he became a member of it, and continued so many years. Pursuing his inclination for music still farther, he became also a member of the Academy of Ancient Music, which used to meet every Thursday evening at the Crown and Anchor in the Strand, but since removed to Freemasons Hall;

Hav us and of this he continued a member till a few years be fore its removal.

Impelled by his own taste for poetry, and excited to it by his friend Foster Webb's example, who had contributed to the Gentleman's Magazine many very elegant poetical compositions, he had, before this time, himself become an occasional contributor in the same kind, as well to that as to some other publications. The earliest of his productions of this species, now known, is supposed to be a copy of verses "To Mr George Stanley, occafioned by looking over fome Compositions of his lately published," which bears date 19th February 1740, and was inserted in the Daily Advertiser for February 21. 1741; but, about the year 1742, he proposed to Mr. Stanley the project of publishing, in conjunction with him, fix cantatas for a voice and instruments, the words to be furnished by himself, and the music by Mr Stanley. The proposal was accepted, the publication was to be at their joint expence, and for their mutual benefit; and accordingly, in 1742, fix cantatas were thus published, the five first written by Mr Hawkins, the fixth and last by Foster Webb; and these having succeeded beyond the most fanguine expectations of their authors, a fecond fet of fix more, written wholly by himself, was in like manner published a few months after, and fucceeded equally well.

As these compositions, by being frequently performed at Vauxhall, Ranelagh, and other public places, and at many private concerts, had become favourite entertainments, many persons, finding the author also a modest well-informed young man of unexceptionable morals, were become defirous of his acquaintance. Among these was Mr Hare of Limehouse, a brewer, who being himself a mufical man, and having met him at Mr Stanley's at musical parties, gave him an invitation to his house: and, to forward him in his profession, introduced him to a friend of his, Peter Storer of Highgate, Esq; which proved the means of making his fortune.

In-the winter of the year 1749, Dr, then Mr Johnfon, was induced to institute a club to meet every Tuefday evening at the King's Head, in Ivy-lane, near St Paul's. It confifted only of nine persons; and Mr. Hawkins was one of the first members. About this time, as it is supposed, finding his father's house, where he had hitherto refided, too fmall for the dispatch of his business now very much encreasing, he, in conjunction with Dr Munckley, a phyfician, with whom he had contracted an intimacy, took a house in Clements-lane, Lombard street. The ground floor was occupied by him as an office, and the first floor by the Doctor as his apartment. Here he continued till the beginning of 1753, when, on occasion of his marriage with Sidney, the youngest of Mr Storer's daughters, who brought him a considerable fortune, he took a house in Austin Friars, near Broad-street, still continuing to follow his profession of an attorney.

Having received, on the death of Peter Storer, Efq. his wife's brother, in 1759, a very large addition to her

fortune, he quitted business to Mr Clark, afterwards Al- Hawkins. derman Clark, who had a short time before completed his clerkship under him, disposed of his house in Austin Friars, and purchased a house at Twickenham. Soon afterwards he bought the lease of one in Hatton-street London, for a town residence.

From a very early period of his life he had entertained a strong love for the amusement of angling; and his affection for it, together with the vicinity of the river-Thames, was undoubtedly his motive to a residence at this village. He had been long acquainted with Walton's Complete Angler; and had, by observation and experience, become himself a very able proficient in the art. Hearing, about this time, that Mr Mofes Browne proposed to publish a new edition of that work, and being himself in possession of some material particulars respecting Walton, he, by letter, made Mr Browne an. offer of writing, for his intended edition, Walton's Life. To this propofal no answer was returned, at least for some time; from which circumstance Mr Hawkins concluded, as any one reasonably would, that his offer was not accepted; and, therefore, having also learnt that Mr Browne meant not to publish the text as the author left it, but to modernize it, in order to file off the rust, as he called it, he wrote again to tell Mr Browne that he understood his intention was to fophiflicate the text, and that therefore he, Mr Hawkins, would himself publish a correct edition. Such an edition, in 1760, he accordingly published in octavo with notes, adding to it a Life of Walton by himself, a Life of Cotton, the author of the fecond part, by the wellknown Mr Oldys; and a fet of cuts defigned by Wale, and engraved by Ryland.

His propenfity to music, manifested by his becoming a member and frequenter of the feveral musical focieties before-mentioned, and also by a regular concert at his house in Austin Friars, had led him, at the time that he was endeavouring to get together a good library of books, to be particularly folicitous for collecting the works of fome of the best musical composers; and, among other acquifitions, it was his fingular good fortune to become possessed by purchase of several of the most scarce and valuable theoretical treatises on the science any where extant, which had formerly been collected by Dr Pepusch. With this flock of enudition, therefore, he, about this time, at the instance of some friends, fet about procuring materials for a work then very much wanted, a History of the Science and Practice of Music, which he afterwards published.

At the recommendation of the well known Paul Whitehead, to the Duke of Newcastle, then Lord Lieutenant for Middlesex, his name was, in 1761, inferted in the Commission of the Peace for that county; and having by the proper studies, and a sedulous atdendance at the fessions, qualified himself for the office, he became an active and useful magistrate in the county(A). Observing, as he had frequent occasion to do in the course of his duty, the bad state of high.

(A) When he first began to act, he formed a resolution of taking no fees, not even the legal and authorised ones, and purfued this method for some time, till he found that it was a temptation to litigation, and that every triffing ale-house quarrel produced an application for a warrant. To check this, therefore, he altered his mode, and received his due fees, but kept them feparately in a purse; and at the end of every summer, before he left the country for the winter, delivered the whole amount to the clergy man of the parish, to be by him distributed among such of the poor as he judged fit.

Hawkins. ways, and the great defect in the laws for amending and keeping them in repair, he fet himfelf to revise the former statutes, and drew an act of parliament consolidating all the former ones, and adding fuch other regulations as were necessary. His sentiments on this subject he published in octavo, in 1763, under the title of "Observations on the State of Highways, and on the Laws for amending and keeping them in repair;" subjoining to them the draught of the act before mentioned; which bill being afterwards introduced into parliament, passed into a law, and is that under which all the highways in England are at this time kept repaired. Of this bill, it is but justice to add, that, in the experience of more than thirty years, it has never required a fingle amendment.

Johnson, and Sir Joshua, then Mr Reynolds, had, in the winter of this year 1763, projecte! the establishment of a club to meet every Monday evening at the Turk's Head, in Gerard fireet; and, at Johnson's solicitation, Mr Hawkins became one of the first members

An event of confiderable importance engaged him, in the year 1764, to stand forth as the champion of the county of Middlefex, against a claim then for the first time fet up, and so enormous in its amount as justly to excite refistance. The city of London finding it necesfary to re-build the gaol of Newgate, the expence of which, according to their own estimates, would amount to L.40,000, had this year applied to parliament, by a bill brought into the House of Commons, in which, on a fuggestion that the county prisoners removed to Newgate for a few days previous to their trials at the Old Bailey, were as two to one to the London prisoners constantly confined there, they endeavoured to throw the burthen of two-thirds of the expence on the county, while they themselves proposed to contribute one third only. I'his attempt the magistrates for Middlesex thought it their duty to oppose; and accordingly a vigorous opposition to it was commenced and supported under the conduct of Mr Hawkins, who drew a petition against the bill, and a case of the county, which was printed and distri buted amongst the members of both houses of parliament. It was the subject of a day's conversation in the House of Lords; and produced such an effect in the House of Commons, that the city, by its own members, moved for leave to withdraw the bill 'The fuccess of this opposition, and the abilities and spirit with which it was conducted, naturally attracted towards Mr Hawkins the attention of his fellow-magistrates; and the chairman of the quarter fessions dying not long after, he was, on the 19th day of September 1765, elected his fuccesfor.

In the year 1771, he quitted Twickenham, and fold his house there to Mr Vaillant; and, in the summer of the next year, for the purpole of obtaining, by fearches in the Bodleian and other libraries, farther materials for his history of music, he made a journey to Oxford, carrying with him an engraver from London, to make drawings from the portraits in the music school.

On occasion of actual tumults or expected disturbances, he had more than once been called into fervice of great personal danger. When the riots at Brentford had arisen, during the time of the Middlesex election in the year 1768, he and some of his brethren attended to suppress them; and, in consequence of an expected riotous

Moorfields in 1769, the magistrates of Middlesex, and Hawkins, he at their head, with a party of guards, attended to oppose them; but the mob, on seeing them prepared, thought it prudent to disperse. In these and other instances, and particularly in his conduct as chairman, having given sufficient proof of his activity, resolution, abilities, integrity, and loyalty, he, on the 23d of October 1772, received from his majesty the honour of knight-

In 1773, Dr Johnson and Mr Stevens published, in ten volumes octavo, their first joint edition of Shakespeare. to which Sir John Hawkins contributed fuch notes as are diftinguished by his name, as he afterwards did a few more on the republication of it in 1778. An address to the king from the county of Middlesex, on occasion of the American war, having, in 1774, been judged expedient, and at his instance voted, he drew up such an address, and, together with two of his brethren, had, in the month of October in that year, the honour of prefenting it.

After sixteen years labour, he, in 1776, published, in five volumes quarto, his General History of the Science and Practice of Music; which, in confequence of permission obtained in 1773, he dedicated to the king, and presented it to him at Buckingham-house on the 14th. of November 1776, when he was honoured with an audience of considerable length both from the king and

Not long after this publication, that is to fax in November 1777, he was induced, by an attempt to rob his house, which, though unsuccessful, was made three different nights with the interval of one or two only between each attempt, to quit his house in Hatton-street; and, after a temporary residence for a short time in St James's Place, he took a leafe of one, formerly inhabited by the famous admiral Vernon, in the street leading up to Queen Square. Westminster, and removed thither.

By this removal he became a constant attendant on Divine worship at the parish-church of St Margaret, Westminster; and having learnt. in December 1778, that the furveyor to the board of ordnance was, in defiance of a provifo in the leafe under which they claimed, carrying up a building at the east end of the church, which was likely to obscure the beautiful painted glass window over the altar there, Sir John Hawkins, with the concurrence of fome of the principal inhabitants, wrote to the furveyor, and compelled him to take down two feet of the wall, which he had already carried up above the fill of the window, and to slope off the roof of his building in fuch a manner, as that it is not only no injury, but, on the contrary, a defence to the win-

In the month of December 1783, Dr Johnson having discovered in himself symptoms of a dropsy, sent for Sir John Hawkins, and telling him the precarious state of his health, declared his defire of making a will, and requested him to be one of his executors. Sir John accepted the office; instructed the Doctor how to make his will: and on his death undertook to be his biographer, and the guardian of his fame, by publishing a complete edition of his works.

Not three months after the commencement of this undertaking, he met with the feverest loss of almost any that a literary man can fustain, short of that of his friends or relations, in the destruction, by fire, of his liaffembly of the journeymen Spital-fields weavers in brary; confifting of a numerous and well chosen colHa ins lection of books, ancient and modern, in many langua- fuccefsfully studied human nature; but he certainly was ges, and on most subjects, which it had been the business of above 30 years at intervals to get together. Of this loss, great as it was in pecuniary value, and comprising in books, prints, and drawings, many articles that could never be replaced, he was never heard in the smallest degree to complain; but having found a temporary reception in a large house in Orchard-street, Westminster, he continued there a short time, and then took a house in the Broad Sanctuary, Westminster.

This event, for a short time, put a stop to the progress of his literary pursuits. As foon, however, as he could sufficiently collect his thoughts, he recommenced his office of biographer of Johnson; and completed his intention by publishing, in 1787, the life and works, in eleven volumes octavo, which he dedicated to the

With this production he terminated his literary labours; and having for many years been more particularly fedulous in his attention to the duties of religion, and accustomed to spend all his leisure from other neceffary concerns in theological and devotional studies, he now more closely addicted himself to them, and set himself to prepare for that event, which he saw could be at no great distance; and the better to accomplish this end, in the month of May 1788, he, by a will and other proper instruments, made such an arrangement of his affairs as he meant should take place after his decease.

In this manner he spent his time till about the beginning of May 1789, when, finding his appetite fail him in a greater degree than usual, he had recourse, as he had fometimes had before on the fame occasion, to the waters of the Islington Spa. These he drank for a few mornings; but on the 14th of that month, while he was there, he was, it is supposed, seized with a paralytic affection, as, on his returning to the carriage which waited for him, his fervants perceived a visible alteration in his face. On his arrival at home, he went to bed, but got up a few hours after, intending to receive an old friend, from whom he expected a visit in the evening. At dinner, however, his diforder returning, he was led up to bed, from which he never rose, on the 21st of the same month, about two in the morning, dying of an apoplexy. He was interred on the 28th in the cloisters of Weilminster Abbey, in the north walk near the eastern door into the church, under a stone, containing, by his express injunctions, no more than the initials of his name, the date of his death, and his age; leaving behind him a high reputation for abilities and integrity, united with the well-earnt character of an active and resolute magistrate, an affectionate husband and father, a firm and zealous friend, a loyal subject, and a fincere Christian.

Such is the character of him in the Biographical Dictionary, which we have neither right nor inclination to controvert. With none of his works are we acquainted but his edition of Walton's Complete Angler, and his Life of Johnson. The former is a very pleafing book; and in the latter are collected many interesting anecdotes of literature and literary men; but they are not well arranged, and the style of the composition is coarse and slovenly. Sir John, we doubt not, was a man of worth, and his reflections on the fentimental slang of Sterne and others, shew that he had

SUPFL. VOL. 1. Part II.

not a man of general taste.

HEAT. See in this Supplement, CHEMISTRY, Part I. chap. v. where we have endeavoured to establish the modern doctrine respecting Caloric or latent heat. In n° 309, &c. of that article, we have given an account of Count Rumford's ingenious experiments, instituted with a view to determine whether or not caloric be a substance, and have stated our reasons for diffenting from his opinion. It has been suggested to us, however, by a friend, to whose judgment we are inclined to pay great deference, that it would be proper, in this place, to give the Count's arguments at full length, and in his own words; and the propriety of this is the more apparent, that in the supplementary article ELECTRICITY, we have hinted our own suspicions of the non-existence of an electrical fluid. The Count then reasons from his experiments in the follow-

" By meditating on the refults of all these experiments, we are naturally brought to that great question which has so often been the subject of speculation among philosophers, namely, What is heat?—Is there any such thing as an igneous fluid?—Is there any thing

that can with propriety be called caloric?

"We have seen that a very considerable quantity of heat may be excited in the friction of two metallic furfaces, and given off in a constant stream or flux in all directions, without interruption or intermission, and without any figns of diminution or exhaustion.

" From whence came the heat which was continually given off in this manner in the foregoing experiments? Was it furnished by the small particles of metal detached from the larger folid masses on their being rubbed together? This, as we have already feen, could not posfibly have been the case.

"Was it furnished by the air? This could not have been the case; for in three of these experiments, the machinery being kept immerfed in water, the access of the air of the atmosphere was completely prevented.

"Was it furnished by the water which surrounded the machinery? That this could not have been the case is evident; first, because this water was continually receiving heat from the machinery, and could not at the fame time be giving to and receiving heat from the fame body; and, fecondly, because there was no chemical decomposition of any part of this water. Had any such decomposition taken place (which indeed could not reasonably have been expected), one of its compound elastic sluids (most probably inflammable air) must at the same time have been set at liberty, and, in making its escape into the atmosphere, would have been detected; but though I frequently examined the water to fee if any air bubbles rose up through it, and had even made preparations for catching them in order to examine them if any thould appear, I could perceive none; nor was there any fign of decomposition of any kind whatever, or other chemical process going on in the water.

" Is it possible the heat could have been supplied by means of the iron bar to the end of which the blunt fteel borer was fixed? or by the fmall neck of gun metal by which the hollow cylinder was united to the cannon? These suppositions appear more improbable even than either of those before mentioned; for heat was

, these last passages, during the whole time the experiment lafted.

"And, in reasoning on this subject, we must not forget to consider that most remarkable circumstance, that the fource of the heat generated by friction in these experiments appeared evidently to be inexhaustible.

"It is hardly necessary to add, that any thing which any infulated body or fystem of bodies can continue to furnish without limitation, cannot possibly be a material fubstance; and it appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of any thing capable of being excited and communicated in the manner the heat was excited and communicated in these experiments, except it be motion.

" But although the mechanism of heat should in fact be one of those mysteries of nature which are beyond the reach of human intelligence, this ought by no means to discourage us, or even lessen our ardour, in our attempts to investigate the laws of its operations. How far can we advance in any of the paths which science has opened to us, before we find ourselves enveloped in those thick mists which on every side bound the horizon of the human intellect? But how ample and interesting is the field that is given us to explore!

"Nobody, furely, in his fober fenses has ever pretended to understand the mechanism of gravitation; and yet what sublime discoveries was our immortal Newton enabled to make, merely by the investigation of the laws of its action! The effects produced in the world by the agency of heat are probably just as extensive and quite as important, as those which are owing to the tendency of the particles of matter towards each other; and there is no doubt but its operations are in all cases determined by laws equally immutable."

HELENA, or ST HELENA. In addition to the account of this island in the Encyclopædia, the following particulars from Sir George Staunton deserve a place in this Supplement, because some of them are important in themselves, while others correct one or two mistakes into which we had fallen, by adopting, implicitly, the narrative of Forster.

The circumference of St Helena measures somewhat less than twenty-eight miles. Along the whole coast to leeward, or to the northward, ships may anchor in perfect fecurity in all feafons of the year, but the bank shelves so abruptly afterwards, that the anchorage, being in deep water, is infecure. The tide feldom rifes above three feet and a half; but the furge of the fea is fometimes tremendous; and feveral accidents happened in approaching or quitting the shore, until a wharf was erected, lately, which renders the arrival there, and departure from it, perfectly safe. In the immediate neighbourhood of the island, storms are little known, thunder is rarely heard, and lightning is feldom perceived.

The steep eminences which intervene between the valleys, that are the chief feats of population, render the communication from one part of this little spot to another slow and difficult. Planters on the windward fide of the island consider a journey to the leeward, or feat of government, as a ferious undertaking. Several of them take that opportunity of paying their respects to the governor, which is called there sometimes "going to court." There are St Helena planters who

Heat, continually going off or out of the machinery, by both have not travelled fo far. At present, by order of the 'Helens, governor, there are fignals fo placed all over the island, as to give instant notice of the approach of vessels to any part of it.

> In the Encyclopædia, it is faid that peaches are the only European fruits which thrive in St Helena; but this appears to be a mistake. Several forts of fruit trees imported into the island had been destroyed by a particular infect; but encouragement has been given for the cultivation of those which that mischievous animal is known to spare, such as the apple, for example, with all the varieties of which it is susceptible. The plantain and banana, or the two species of the musa, thrive also remarkably well. The ground is fertile, and in favourable feafons produces, in fome instances, double crops within the year. Plantations, however, of cotton, indigo, or canes, were not found to answer: though some good coffee has been produced in it. A botanic garden has been established near the governor's country house. An intelligent gardener has been sent to take care of it by the company; and a vast variety of trees, plants, and flowers of different, and fometimes opposite climates, are already collected in it. The furrounding sea abounds in esculent fish; and seventy different species, including turtle, have been caught upon the coasts. Whales are feen in great numbers playing round the island, where it is supposed the southern whale fishery might be carried on to great national ad-

> The country is chiefly cultivated by blacks. Perfons of that colour were brought in a flate of flavery to it by its first European settlers; and it seldom happens that white men will fubmit to common work where there are black slaves to whom it may be transferred. These were for a long time under the unlimited dominion of their owners, until a representation of the abuses made of that power induced the India Company to place them under the immediate protection of the magistracy, and to enact various regulations in their favour; which have contributed to render them, in a great degree, comfortable and fecure. These regulations may have hurt, at first, the feelings of the owners of flaves, but not their real interest; for it appears, that before their introduction there was a lofs, upon an average, of about ten in a hundred flaves every year, to be fupplied at a very heavy expence; whereas, under the present system, they naturally increase. All future importation of flaves into the island is prohibited.

> · Besides the blacks in a state of slavery, there are fome who are free. 'The labour of these tending to diminish the value of that of slaves, the free blacks became once obnoxious to fome flave owners; who had fufficient influence, in a grand jury, to present them as without visible means of gaining a livelihood, and liable to become burdensome to the community; but upon examination, it appeared that all free blacks of age to work were actually employed; that not one of them had been tried for a crime for feveral years, nor had any of them been upon the parish. They are now by the humane interpolition of the company placed under the immediate protection of the government, and put nearly upon a footing with the other free inhabitants, who, when accused of crimes, have the privilege of a jury, as well as in civil causes.

The principal fettlement of St Helena has the pcculiar advantage of uniting the shelter of a leeward situation with the coolness of windward gales. The fouth-east wind blows constantly down the valley, rendering a refidence in it pleafant as well as healthy. The country is so fertile, and the climate so congenial to the human feelings, that perhaps it would be difficult to find out a fpot where perfons, not having acquired a relish for the enjoyments of the world, or already advanced in life, and furfeited with them, could have a better chance of protracting their days in eafe, health, and comfort.

HELICOID PARABOLA, or the Parabolic Spiral, is a curve arising from the supposition that the common or Apollonian parabola is bent or twisted, till the axis come into the periphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in

the fame plane.

HELISPHERICAL LINE, is the Rhumb line in Navigation; being fo called, because on the globe it winds round the pole helically or spirally, coming still nearer and nearer to it.

HENIOCHAS, or Heniochus, a northern constellation, the same as Auriga, which see Encycl.

HERSCHEL, the name by which the French, and most other European nations, call the new planet difcovered by Dr Herschel in the year 1781. Its mark or character is 11. The Italians call it Ouranos, or Urania; but the English, the Georgian Planet, or Georgium Sidus.

HETERODROMUS VECTIS, or LEVER, in Mechanics, a lever in which the fulcrum, or point of fufpension, is between the weight and the power; being the same as what is otherwise called a lever of the first

HINZUAN, the proper name of one of the Comora islands, which by different writers of different nations has been called Anzuame, Anjuan, Juanny, and Johanna, and which is described in the Encyclopædia under the name of ST JOANNA. In that article, it is observed, that an anonymous writer has censured the descriptions of this island given by the Abbé Reynal and Major Rooke, as being not only exaggerated, but erroneous; neither the country being so picturesque as the former reprefents it, nor the inhabitants meriting the respectable character given of them by the latter.

There was not perhaps much propriety in admitting into fuch a work as the Encyclopædia Britannica, the anonymous cenfure of descriptions, authenticated by the names of respectable authors; but the best reparation which we can make to those authors, is, to inform our readers, that their descriptions of Hinzuan are confirmed by Sir William Jones, whose testimony, we believe, no man will controvert. That accomplished scholar, who visited the island on his voyage to India, thus describes its appearance from the bay in which the ship

rode at anchor.

"Before us was a vast amphitheatre, of which you may form a general notion by picturing in your minds a multitude of hills infinitely varied in fize and figure, and then supposing them to be thrown together, with a kind of artless symmetry, in all imaginable positions. The back ground was a feries of mountains, one of which is pointed, near half a mile perpendicularly high

from the level of the sea, and little more than three Hinzuan. miles from the shore: all of them richly clothed with wood, chiefly fruit trees, of an exquisite verdure. I had feen many a mountain of stupendous height in Wales and Swifferland, but never faw one before, round the bosom of which the clouds were almost continually rolling, while its green fummit rofe flourishing above them, and received from them an additional brightness. Next to this distant range of hills was another tier, part of which appeared charmingly verdant, and part rather barren; but the contrast of colours changed even this nakedness into a beauty: nearer still were innumerable mountains, or rather cliffs, which brought down their verdure and fertility quite to the beach; fo that every shade of green, the sweetest of colours, was displayed at one view by land and by water. But nothing conduced more to the variety of this enchanting prospect, than the many rows of palm trees, especially the tall and graceful Arecas, on the shores, in the valleys, and on the ridges of hills, where one might almost suppose them to have been planted regularly by design. more beautiful appearance can scarce be conceived, than fuch a number of elegant palms in fuch a fituation, with luxuriant tops, like verdant plumes, placed at just intervals, and showing between them part of the remoter landscape, while they left the rest to be supplied by the beholder's imagination. The town of Matfamúdò lay on our left, remarkable at a distance for the tower of the principal mosque, which was built by Halimah, a queen of the island, from whom the prefent king is descended: a little on our right was a small town, called Bantani. Neither the territory of Nice, with its olives, date trees, and cypresses, nor the isles of Hieres, with their delightful orange groves, appeared fo charming to me, as the view from the road of Hin-

Sir William Jones, speaking of the inhabitants, takes notice of the Lords, Dukes, and Princes, of whom we have made mention after Major Rooke. "The frigate, (fays he) was prefently furrounded with canoes, and the deck foon crowded with natives of all ranks, from the high born chief, who washed linen, to the halfnaked flave, who only paddled. Most of them had letters of recommendation from Englishmen, which none of them were able to read, though they fpoke English intelligibly; and fome appeared vain of titles, which our countrymen gave them in play, according to their supposed stations: we had Lords, Dukes, and Princes on board, foliciting our custom, and importuning us for presents. In fact, they were too sensible to be proud of empty founds, but justly imagined, that those ridiculous titles would ferve as marks of diffinction, and, by attracting notice, procure for them fomething fubstantial." He speaks with great respect of the king, whose name was chmed, as well as of several chiefs whom he faw, and feems to have met with no man of rank on the island whose character was contemptible, but Selim the king's eldest son. For the behaviour of that prince, the old fovereign made the best apology that he could, while he privately affured the interpreter, that he was much displeased with it, and would not fail to express his displeasure. He concluded his conversation with a long harangue on the advantage which the English might derive from sending a ship every year from Bombay to trade with his subjects, and on

Hinzuar. the wonderful cheapness of their commodities, especially of their cowries. Ridiculous as this idea might feem, it showed (fays Sir William) an enlargement of mind, a defire of promoting the interest of his people, and a fense of the benefits arising from trade, which could hardly have been expected from a petty African chief, and which, if he had been fovereign of Yemen, might have been expanded into rational projects pro-

portioned to the extent of his dominions.

The master of the frigate learned from one of the chiefs a few curious circumstances concerning the government of Hinzuan; which he found to be a monarchy limited by an aristocracy. The king, he was told, had no power of making war by his own authority; but, if the affembly of nobles, who were from time to time convened by him, refolved on a war with any of the neighbouring islands, they defrayed the charges of it by voluntary contributions; in return for which, they claimed as their own all the booty and captives that might be taken. The hope of gain or the want of slaves is usually the real motive for such enterprises, and oftenfible pretexts are eafily found: at that very time, he understood they meditated a war, because they wanted hands for the following harvest. Their fleet confifted of fixteen or feventeen fmall veffels, which they manned with about two thousand five hundred islanders, armed with muskets and cutlasses, or with bows and arrows. Near two years before they had possessed themselves of two towns in Mayata, which they fill kept and garrifoned. 'The ordinary expences of the government were defrayed by a tax from two hundred villages; but the three principal towns were exempt from all taxes, except that they paid annually to the chief Mufti a fortieth part of the value of all their moveable property, and from that payment neither the king nor the nobles claimed an exemption. The kingly authority, by the principles of their conftitution, was confidered as elective, though the line of fuccession had not in fact been altered fince the first election of a fultan.

Sir William Jones concludes his remarks on this island with some reflections; of which, though they may be confidered as digressive, we are persuaded our readers

will approve of our extending the circulation.

" We have lately heard of civil commotions in Hinzuan, which, we may venture to pronounce, were not excited by any cruelty or violence of Ahmed, but were probably occasioned by the infolence of an oligarchy naturally hostile to king and people. That the mountains in the Comara islands contain diamonds, and the precious metals, which are studiously concealed by the policy of the feveral governments, may be true, though I have no reason to believe it, and have only heard it afferted without evidence; but I hope, that neither an expectation of fuch treasures, nor of any other advantage, will ever induce an European power to violate the first principles of justice by affuming the sovereignty of Hinzuan, which cannot answer a better purpose than that of fupplying our fleets with feafonable refreshment; and, although the natives have an interest in receiving us with apparent cordiality, yet, if we wish their attachment to be unfeigned and their dealings just, we must fet them an example of strict honesty in the performance of our engagements. In truth, our

nation is not cordially loved by the inhabitants of Fin. Hinzhan zuan, who, as it commonly happens, form a general opinion from a few instances of violence or breach of Hirudo, faith. Not many years ago an European, who had been hospitably received and liberally supported at Matfamudo, behaved sudely to a young married wo. man, who, being of low degree, was walking veiled through a street in the evening: her husband ran to protect her, and refented the rudeness, probably with menaces, possibly with actual force; and the European is faid to have given him a mortal wound with a knife or bayonet, which he brought, after the fcuffle, from his lodging. This foul murder, which the law of nature would have justified the magistrate in punishing with death, was reported to the king, who told the governor (I use the very words of Alwi a cousin of the king's), that " it would be wifer to hush it up." Alwi mentioned a civil case of his own, which ought not to be concealed. When he was on the coast of Africa in the dominions of a very favage prince, a small European veffel was wrecked; and the prince not only feized all that could be faved from the wreck, but claimed the captain and the crew as his flaves, and treated them with ferocious infolence. Alwi affured me, that, when he heard of the accident, he haftened to the prince, fell proftrate before him, and by tears and importunity prevailed on him to give the Euro. peans their liberty; that he supported them at his own expence, enabled them to build another veffel, in which they failed to Hinzuan, and departed thence for Europe or India: he shewed me the captain's promissory notes for fums, which to an African trader must be a confiderable object, but which were no price for liberty, fafety, and, perhaps, life, which his good, though difinterested, offices had procured. I lamented, that, in my fituation, it was wholly out of my power to affift Alwi in obtaining justice; but he urged me to deliver an Arabic letter from him, enclosing the notes, to the governor general, who, as he faid, knew him well; and complied with his request. Since it is possible, that a substantial defence may be made by the person thus accused of injustice, I will not name either him or the veffel, which he had commanded; but, if he be living, and if this paper should fall into his liands, he may be induced to reflect how highly it imports our national honour, that a people, whom we call favage, but who administer to our convenience, may have no just cause to reproach us with a violation of our contracts."

HIPS, in architecture, are those pieces of timber placed at the corners of a roof. These are much longer than the rafters, because of their oblique position. Hip means also the angle formed by two parts of the roof,

when it rifes outwards.

HIP-Roof, called also Italian roof, is one in which two parts of the roof meet in an angle, rifing outwards: the fame angle being called a valley, when it finks inwards.

HIRCUS, in aftronomy, a fixed flar of the first mag-

nitude, the fame with capella.

Hircus is also used by some writers for a comet, encompassed as it were with a mane, seemingly rough and

HIRUDO. Sce Encycl. A new species of this inseet was discovered in the South Sea by Le Martiniere, naturalist in Perouse's voyage of discovery. He found Hi do it buried about half an inch in a shark's liver, but could deed not found at all in Java, appears to have been the Hispanio's not conceive how it had got thither. It was fomething more than an inch long, of a whitish colour, and composed of several rings similar to those of the tænia. The superior part of its head was furnished with four small ciliated mamillæ, by which it took its food; under each manuilla on both fides was a fmall oblong pouch, in the form of a cup; and in the form of its instrumenta cibaria, it very nearly refembles the animal which has been supposed to be the cause of measles in swine. Both these species are referable to the genus birudo, the chavacters of which, as given by Linnæus, stand (says Martiniere) in need of reformation.

HIRUNDO ESCULENTA (see HIRUNDO, Encycl. nº 3.), is thus described in the Transactions of the Batavian Society in the Island of Java, vol. iii.; and the description confirms the sagacious conjecture of Mr Latham respecting the fize of the bird, which the rea-

der will find in our article referred to.

"The hirundo esculenta is of a blackish grey colour, inclining a little to green; but on the back to the tail, as well as on the belly, this blackish colour gradually changes into a mouse colour. The whole length of the bird from the bill to the tail is about four inches and a half, and its height from the bill to the extremity of in the island of St Domingo; but in that eventful year, the middle toe three inches and a quarter. The distance the slame, which had burst forth in Europe, spread it. from the tip of the one wing to that of the other, when extended, is ten inches and a quarter. The largest feathers of the wings are about four inches in length. proportion to the rest of the body. The bill is broad, its detestation of every kind of slavery, as well as of the infects that serve it for food. The eyes are black, and of a confiderable fize. The tongue, which is not forked, is shaped like an arrow. The ears are flat, round, naked spots, with small oblong openings, and are entirely concealed under the feathers of the head. The neck is very short, as well as the legs and the bones of the wings. The thighs are wholly covered with feathers; and the very tender lower parts of the legs, and the feet themselves, are covered with a skin like black parchment. Each foot has four toes, three of which are before and one turned backwards. They are all detached from each other to the roots; and the middle one, together with the claw, is fully as long as the lower part of the leg. Each toe is furnished with a black, sharp, crooked claw of a confiderable length, by which the animal can with great facility attach itself to crags and rocks. The tail is fully as long as the body together with the neck and the head. When expanded it has the form of a wedge, and consists of ten large feathers. The four first on each side are long; and, when the tail is closed, extend almost an inch beyond the rest. The other feathers decrease towards the middle of the tail, and are equal to about the length of the body."

There is a variety of this species of hirundo, with a speckled breast, and white spots on the tail feathers; and this, though less numerous than the other, and in-

only hirundo esculenta known to Linnæus. For an account of the eatable ness of these birds, and the manner of collecting them, see CAP and BUTTON in this Supplement.

HISPANIOLA, or ST Domingo, the largest of the Antilles or Caribbee islands, has been described, as it existed prior to the French revolution, in the Encyclopadia. Previous to the year 1789 the government of the French part of the illand was administered by an officer called the Intendant, and a Governor-General, both nominated by the crown, and invefted with authority for three years. Their powers were in some cases diffinct, and in others united; but though these powers were extensive and almost absolute, the attention which the old government of France paid to the character and rank of those persons whom it had placed over its foreign fettlements, fecured to the inhabitants of Hispaniola a very confiderable share of happiness. In spite of what our reftlefs innovators call political evils, figns of prosperity were everywhere visible; their towns were opulent, their markets plentiful, their commerce exten-

five, and their cultivation increasing.

Such was, in 1788, the state of the French colony felf to the West Indies. An affociation had been formed in France upon principles somewhat similar to those of our fociety for the abolition of the slave trade; but The head is flat; but, on account of the thickness of that affociation, which called itself Amis des Noirs, had the feathers, appears round, and to be of a large fize in much more dangerous defigns than ours. Avowing and ends in a sharp extremity, bent downwards in the African trade, and condemning those abettors of liber-form of an awl. The width of it is increased by a ty who dared to declare themselves possessors of men, naked piece of skin somewhat like parchment, which, its members kept up an intimate and clandestine conwhen the bill is shut, lies folded together; but which, nection with those rich mulattoes who resided in France when the bill opens, is considerably extended, and enables for their education, and laboured to convince them that the bird to catch with greater ease, while on wing, the neither their colour nor their spurious birth should make any civil or political diffinction between them and the whites who were born in wedlock. 'To co-operate, as it were, with thefe factious and false doctrines, the National Affembly issued its famous declaration, in which it was maintained that all mankind are born, and continue free, and equal in their rights. The confequence of this was fuch as might have been expected. The mulattoes of Hispaniola instructed in the French philosophy of the rights of man, broke out into rebellion; but not acting in concert, they were quickly overpowered.

The spirit, however, which had been excited among them, still continued to ferment; and the National Affembly of France, taking the state of the island into solemn confideration, decreed, by a great majority, that its intention had never been to intermeddle with the internal affairs of the colony; that their internal legislation was entirely their own; and that the legislature of the mother country would make no innovation, directly or indirectly, in the fystem of commerce in which the colonies were already concerned. However grateful this declaration might be to the whites of St Domingo, and in the then state of things however wife in itself, it occasioned discontent and remonstrances on: the part of the factious friends of the negroes. They regarded it as an unwarrantable fanction of the African

Hispaniola traffic, and a confession, that the planters of Hispaniola were not colonists, but an independent people.

The colonists themselves, indeed, or rather their representatives, seem to have thought that by this decree they were rendered independent; for in their general affembly they paffed an act debarring the king's delegate, the governor general, from negativing any of their future acts. This violent measure was far from giving universal satisfaction. The western parishes recalled their delegates, while those of Cape François renounced their obedience to the whole affembly, and petitioned the governor to dissolve it.

During these diffensions, the commander of a ship of the line, which lay in the harbour of Port-au-Prince, gave a sumptuous entertainment to the friends of the governor; on which account the feamen, who declared themselves in the interest of the assembly, thought fit to mutiny; and the affembly, in return, voted their thanks to the mutineers. Some of their partizans, feizing at the same time a powder magazine, the governor declared them adherents to traitors, and called on all officers, civil and military, to bring them to punishment. This was the fignal for civil infurrection; armed troops took the field on both fides; and war feemed inevitable, when the affembly resolved to repair in a body to France

and justify their past conduct.

In the mean time the Amis des Noirs contrived to excite the people of colour to rebellion. They initiated in the doctrine of equality and the rights of man one James Oge, then residing in Paris in some degree of affluence. They persuaded him to go to St Domingo, put himself at the head of his people, and deliver them from the oppression of the whites; and in order to evade the notice of government, they undertook to procure for him arms and ammunition in America. He embarked accordingly, July 1790, for New England with money and letters of credit; but notwithstanding the caution of the Amis des Noirs, his designs were discovered by the French government, and his portrait was fent out before him to St Domingo. He landed on the island in October, and six weeks afterwards published a manifesto, declaring his intention of taking up arms, if the privileges of whites were not granted to all persons -without distinction. He was joined by about 200 men of colour; and this little army of ruffians not only maffacred the whites wherever they fell in with them in small numbers, but, by a still more unjustifiable mode of conduct, took vengeance on those of their own colour who refused to join their rebellious standard. They were, however, foon overpowered by the regular troops; and their leader, after disclosing, it is said, some important secrets, suffered the punishment due to his treason.

While these things were going on in the island, the members of the Colonial Assembly arrived at Paris, where they were received by the representatives of the French people with marked fymptoms of averfion. The resolutions composing their famous decree were pronounced improper; their vote of thanks to the mutineers was declared criminal; they were themselves perfonally arrested; orders were given for a new affembly to be called; and the king was requested to augment the naval and military force then at St Domingo.

The National Affembly of France having decreed that every person twenty-five years old and upwards, pos-

fessing property, or having resided two years in the co. Hispanials lony and paid taxes, should be permitted to vote in the formation of the colonial affembly, the people of colour very naturally concluded that this privilege was conferred upon them. Such, however, we believe, was not the meaning of the National Affembly; but Gregoire, with the other friends of the negroes, at last prevailed, and mulattoes born of free parents were pronounced to be not only worthy of choosing their representatives, but also eligible themselves to seats in the colonial assemblies. This decree facrificed at once all the whites in the island to the people of colour; and the indignation which filled the minds of both the royal and the republican parties feemed to have united them in one common cause. They refolved to reject the civic oath; to confifcate the French property in the harbour, on which they actually laid an embargo; to pull down the national colours, and to hoist the British standard in their stead. The mulattoes in the mean time collected in armed bodies, and waited with anxious expectation to fee what measures the colonial affembly would adopt.

During these diffensions, the negro slaves, into whose minds had been feduloufly instilled an opinion that their rights were equal to those of their masters, resolved to recover their freedom. On the morning of the 23d of August 1791, the town of the Cape was alarmed by a confused report that the slaves in the adjoining parishes had revolted; and the tidings were foon confirmed by the arrival of those who had narrowly escaped the massacre. The rebellion had broken out in the parish of Acul, nine miles from the city, where the whites had been butchered without distinction; and now the rebels proceeded from parish to parish, murdering the men, and ravishing the unfortunate women who fell into their hands. In a short time the sword was accompanied with fire, and the cane-fields blazed in every direction The citizens now flew to arms, and the command of the national troops was given to the governor, whilst the women and children were put aboard the ships in the harbour for fafety. In the first action the rebels were repulfed; but their numbers rapidly increasing, the governor judged it expedient to act folely on the defensive. In the space of two months it was computed that upwards of 2000 white persons perished; and of the infurgents, who confifted as well of mulattoes as of negroes, not fewer than 10,000 died by famine and the fword, and hundreds by the hands of the executioner.

When intelligence of these dreadful proceedings reached Paris, the Affembly began to be convinced that its equalizing principles had been carried too far; and the famous decree, which put the people of colour on the fame footing with the whites, was repealed. commissioners were likewise sent to the colony to restore peace between the whites and the mulattoes; but two of them being men of bad character, and none of them possessing abilities for the arduous task of extinguishing the flames of a civil war, they returned to France without accomplishing in any degree the object of their

mission.

In the mean time the Amis des Noirs in the mother country had once more gained the ascendant in the National Affembly; and three new commissioners, Santhonax, Polverel, and Ailhaud, with 6000 chosen men from the national guards, were embarked for St DoHi niola mingo. It was strongly suspected that the object of enemy, to abandon the island, which is now under the Hollow, these commissioners was to procure unqualified freedom for all the blacks in the island; but they solemnly swore that their fole purpose was to establish the rights of the mulattoes, as decreed by the law which had been lately repealed. The whites therefore expected that a colonial affembly would be convoked; but inflead of this the commissioners nominated twelve persons, of whom fix had been members of the last affembly, and fix were mulattoes, Une Commission Intermediare, with authority to raife contributions on the inhabitants, the application of which, however, they referved to themselves. The governor finding that the commissioners usurped all authority, complained that he was but a cypher in public affairs; his complaint was answered by an arrest upon his person, and he was sent a state prisoner to France.

The tyranny of the commissioners did not stop here. They overawed the members of the commission intermediare, by arresting four of their number; and difagreeing among themselves, Santhonax and Polverel difmissed Ailhaud from their councils. War was by this time declared between the mother country and Great Britain, and prudence compelled the government of France to take some care of the injured colony. Galbaud, therefore, a man of fair character, was appointed governor, and ordered to put the island in a state of defence against foreign invasion; but possessing West India property, which it feems was a legal disqualification for the office of governor, the commissioners difregarded his authority, and took up arms against him. Finding themselves likely to be worsted, they offered to purchase the aid of the rebel negroes, by the offer of a pardon for their past conduct, freedom in future, and the plunder of the capital. Two of the negro chiefs, more honourable than the French commissioners, spurned at the base proposal; but a third, after the governor had fled to the ships, entered the town with 3000 revolted negroes, and began an indifcriminate massacre. The miferable inhabitants fled to the shore, but their retreat was stopped by a party of mulattoes; and for two days the slaughter was incessant. The town was half confumed by fire; and the commissioners, terrified at the work of their own hands, fled for protection to a ship of the line, and thence issued a manifesto, which, while it tried to extenuate, evinced a consciousness of their

Thus was loft perhaps to Europe, and loft by the frantic conduct of French philanthropists, the finest island in the West Indies; an island which produced alone as much fugar as all the British West India posfessions united; not to mention the coffee and indigo, which were in immense quantities cultivated in Hispaniola. Had it not been for the restless machinations of the Amis des Noirs, it does not appear that so general a revolt would have taken place among the flaves; for though the spirit of republicanism had found its way into the island, the republicans joined with the royalists to keep the negroes in proper subjection. The unsuccelsful attempt which, at the request of the more refpectable part of the inhabitants, the British government made to fubdue the execrable commissioners and their adherents, is fresh in the memory of all our readers, and need not here be detailed at length. Suffice it to fay, that after prodigies of valour, our troops were compelled, rather by disease than by the swords of the beings, and on Divine Providence, religion, and reli-

controul of a negro or mulatto-chief. What will ulti- Holwell. mately become of it, future events must decide; but let its protracted and bloody disputes be a warning to all, and among others to our affociation for the abolition of the flave trade, that it is impossible to promote a good end by wicked means, and that flaves must be civilized before they be made free.

HOLLOW, in architecture, a concave moulding, about a quarter of a circle, by some called a casement,

by others an abacus.

Hollow-Tower, in fortification, is a rounding made of the remainder of two brifures, to join the curtain to the crillon, where the small shot are played, that they may not be so much exposed to the view of the enemy.

HOLWELL (John Zephaniah, Efq;), was a gen-

tleman of letters, whose history is well intitled to a place in fuch a collection as ours; but, unfortunately, we know not either the time or the place of his birth, or the fchool at which he was educated. At an early period of life he was fent to Bengal as a writer in the East-India Company's fervice, and in the year 1756, was fecond in council at Fort William, when an offence was given to the nabob of Bengal by the governor's protecting a fugitive native. In revenge for this, the nabob marched against the fort with a powerful army. Drake, the chief who had given the offence, deferted his station, and the command devolved on Mr Holwell, who, with the few men he had, defended the place to the last extremity. This opposition incenfed the nabob against Mr Holwell; and although on the furrender he had given his word that no harm should come to him, Mr Holwell and his unfortunate fellows in arms were thrust into a close prison, called the Black Hole *, not * See CAZeighteen feet square, to the number of 146 persons, and cutta, into which no supply of air could come but by two Encycl. fmall windows in one end. Here for one whole night they were confined; the numbers crowded together caufed a most profuse perspiration, which was succeeded by a raging thirst. They called for water, but the little fupply which the humanity of the black foldiers could grant them, was nearly all lost in the struggle to obtain it. Every few minutes some one or other expired, through thirst, or pressure, or were trampled to death. Mr Holwell, after struggling for many hours, threw himself down on a platform, and in a short space of time happily became infenfible. In this difmal dungeon they were kept till fix o'clock in the morning, when twenty-three only were found alive. Mr Holwell himself was in a high fever, but was loaded with fetters and otherwise ill treated, yet the excellency of his constitution overcame all his hardships, and he was soon after released and embarked for England. In 1758 he published a well written and affecting narrative of the fufferings of himself and his companions. Since thistime Mr Holwell has refided in England, and has written several tracts on Indian affairs, particularly a work. in three parts, intitled " Events relative to Bengal and Hindostan."-" The manner of inoculating for the fmall pox in the East Indies."--" A new experiment for the prevention of crimes," published in 1786. He has also published a tract which contains some very singular fentiments on religious subjects, intitled "Differtations on the origin, nature, and purfuits of intelligent

Memodro- gious worship." Mr Holwell was elected many years description of an ellipse round the focus, owing to his Hooks ago, F. R. S. and lived to a good old age, respected by his acquaintance, and although much afflicted by bodily complaints, possessed a wonderful fund of spirits.

HOMODROMUS VECTIS, or Lever, in mechanics, is a lever in which the weight and power are both on the same side of the fulcrum as in the lever of the 2d and 3d kind; being so called, because here the weight and power move both in the same direction, whereas in the heterodromus they move in opposite directions.

HOOKE (Dr Robert) is faid, in the account of him which is published in the Encyclopadia, to have laid claim to the inventions of others, and to have boafted of many of his own, which he never communicated. We will not presume to fay that this charge is entirely groundless; but we know that it has been greatly exaggerated, and that many discoveries undoubtedly made by him have been claimed by others. Of this the reader will find one conspicuous proof under the article WATCH (Encycl.); and perhaps the following history of the inventions to which he laid claim may furnish another. It would be harsh to charge him with falsity in any of them; that is to fay, to imagine that he either stole them from others, or did not think, at least, that he was an inventor. And, with respect to many of them, the priority of his claim is beyond dispute.

1656, Barometer, a weather glass.

1657, A scapement, for maintaining the vibration of a pendulum. - And not long after, the regulating or

balance-spring for watches.

1658, The double barrelled air-pump. - The conical pendulum.-His first employment of the conical pendulum was no less ingenious and scientific than it was original. He employed it to represent the mutual gravitation of the planets; a fact which he had most systematically announced. He had shewn, that a force, perfectly analogous to gravity on this earth, operated on the surface of the moon and of Jupiter. Confidering the numerous round pits on the furface of the moon, furrounded with a fort of wall, and having a little eminence in the middle, as the production of volcanoes, he inferred, that the ejected matter fell back again to the moon, as fuch matter falls back again to the earth. He faw Jupiter furrounded with an zatmosphere, which accompanied him; and therefore prefs fed on him, as our air presses on the earth:-He inferred, that it was the same kind of power that maintained the fun and other planets in a round form. He inferred a force to the fun from the circulation round him, and he called it a gravitation; and faid that it was not the earth which described the ellipse, but the centre of gravity of the earth and moon. He therefore made a conical pendulum, whose tendency to a vertical position represented the gravitation to the fun, and which was projected at right angles to the vertical plane; and shewed experimentally, how the different proportions of the projectile and centripetal tendencies produced various degrees of eccentricity in the orbit. He then added another pendulum, describing a cone round the first, while this described a cone round the vertical line, in corder to fee what point between them described the ellipse. The results of the experiment were intricate and unsatisfactory; but the thought was ingenious. He candidly acknowledged, that he had not discovered the true law of gravitation which would produce the

want of due mathematical knowledge; and therefore left this investigation to his superiors. Sir Isaac Newton was the happy man who made the discovery, after having entertained the same notions of the forces which connected the bodies of the folar fystem, before he had any acquaintance with Dr Hooke, or knew of his speculations.

1660, The engine for cutting clock and watch wheels. -The chief phenomena of capillary attraction.-The

freezing of water a fixed temperature.

1663, The method of supplying air to a diving bell. -The number of vibrations made by a mufical chord.

1664, His Micrographia was, by the council of the Royal Society, ordered to be printed; but in that work are many just notions respecting respiration, the composition of the atmosphere, and the nature of light, which were afterwards attributed as discoveries to Mayow and others, who, though we are far from suppofing that they stole their discoveries from Dr Hooke, were certainly anticipated by him.

1666, A quadrant by reflection.

1667, The marine barometer .- The gage for found. ing unfathomable depths.

1668, The measurement of a degree of the meridian, with a view to determine the figure of the earth, by means of a zenith fector.

1669, The fact of the conservatio virium vivarum. and that in all the productions and extinctions of motion, the accumulated forces were as the squares of the final or initial velocities. This doctrine he announces in all its generality and importance, deducing from it all the confequences which John Bernoulli values himfelf so highly upon, and which are the chief facts adduced by Leibnitz in support of his doctrine of the forces of bodies in motion. But Hooke was perfectly aware of their entire correspondence with the Cartesian, or common doctrine, and was one of the first in applying the celebrated 39th proposition of Newton's Principia to his former positions on this subject, as a mathematical demonstration of them.

1673, That the catenarea was the best form of an

1674, Steam engine on Newcomen's principle.

1679, That the air was the fole fource of heat in burning: That combustion is the folution of the inflammable vapour in air; and that in this folution the air gives out its heat and light. That nitre explodes and causes bodies to burn without air, because it consides of this air, accompanied by its heat and light in a condensed or solid state; and air supports stame, because it contains the same ingredients that gunpowder doth, that is, a nitrous spirit: That this air dissolves something in the blood while it is exposed to it in the lungs in a very expanded furface, and when faturated with it, can no longer support life nor flame; but in the act of folution, it produces animal heat: That the arterial and venal blood differ on account of this fomething being wanting in one of them. In short, the fundamental doctrines of modern chemistry are systematically delivered by Dr Hooke in his Micrographia, published in 1664, and his Lampas, published in 1677.

1680, He first observed the secondary vibrations of elastic bodies, and their connection with harmonic founds. A glass containing water, and excited by a fiddlestick,

ok, threw the water into undulations, which were fquare; and pleasant. Having been for some years a tutor at Horne. hexagonal, octagonal, &c. shewing that it made vibrations subordinate to the total vibration; and that the fundamental found was accompanied by its octave, its twelfth, &c.

1681, He exhibited musical tones by means of tooth. ed wheels, whirled round and rubbed with a quill, which dropped from tooth to tooth, and produced tones proportioned to the frequency of the cracks or fnaps.

1684, He read a paper before the Royal Society, in which he affirms, that fome years before that period he had proposed a method of discoursing at a distance, not by found, but by fight. He then proceeds to describe a very accurate and complete telegraph, equal, perhaps, in all respects to those now in use. years previous to 1684, M. Amontans, had not invented his telegraph; fo that, though the Marquis of Worcester unquestionably gave the first hint of this instrument, Dr Hooke appears to have first brought it to perfection. See Telegraph, Encycl.; and a book, published 1726, entitled Philosophical Experiments and Observations of the late eminent Dr Robert Hooke.

We are indebted to him for many other discoveries of leffer note; such as the wheel barometer, the univerfal joint, the manometer, screw divided quadrant, telescopic fights for astronomical instruments, representation of a muscular fibre by a chain of bladders, experiments shewing the inflection of light, and its attraction for folid bodies, the curvilineal path of light thro'

the atmosphere.

HORNE (George, D. D.), late Lord Bishop of Norwich, was a man of fuch amiable dispositions, primitive piety, and exemplary morals. that we wish it were in our power to do justice to his character. His life, it is true, has been already written, at confiderable length, by two authors, possessed of erudition and of unquestionable integrity; but mere erudition is by no means sufficient to sit a man for discharging the duties of a biographer. It was not the learning of Johnson, but his fagacity, and intimate acquaintance with human nature, that placed him fo far above his contemporaries in this department of literature.

Of Bishop Horne's biographers, one possessed, indeed, the great advantage of having lived in habits of intimacy with him from his boyish years. In the authenticity of his narrative, therefore, the fullest confidence may be placed: and that narrative we shall faithfully follow; referving, however, to ourselves the liberty of sometimes making reflections on the various incidents recorded, widely different from those of the au-

George Horne was, in 1739, born at Otham in Kent, a village near Maidstone, giving the name to a parish, of which his father was the rector. He was the fecond of four fons; of whom the eldest died in very early life, and the youngest, who is still alive, succeeded his father both in the rectory of Otham and in that of Breda in the county of Suffex. He had likewise three fifters, of whose fortunes we know nothing.

Mr Horne, the father of the family, was of a temper so remarkably averse from giving pain or trouble upon any occasion, that he used to awake his fon George, when an infant, by playing upon a flute, that the change from sleeping to awaking might be gradual

SUPPL. VOL. I. Part II.

Oxford, he took upon himself the early part of the classical education of this favourite son; an office of which he was well qualified to discharge the duties. Under such an instructor, the subject of this memoir lcd a very pleafant life, and made a rapid progress in the Greek and Latin languages. By the perfuafion of a friend, however, he was, at the age of thirteen, placed in the school of Maidstone, then under the care of a Mr Bye, eminent for his knowledge of ancient literature. And remaining with this gentleman two years, he added much to his flock of learning; and, among other things, a little elementary knowledge of the Hebrew tongue, which Mr Bye taught on the plan of Buxtorf. Though Dr Horne afterwards rejected that plan, he readily admitted, that the knowledge of it was of great advantage to him.

At the age of fifteen, he was removed from Maidflone fehool to Univerfity college Oxford, where his father had happily obtained for him a scholarship. At college his fludies were, in general, the fame with those of other virtuous and ingenious youths; while the vivacity of his conversation, and the propriety of his conduct, endeared him to all whose regard was creditable. About the time of his taking his bachelor's degree, he was chosen a fellow of Magdalen College; and foon af-

terwards, if not before, commenced author.

The history of his authorship is curious, and we shall give it at some length. While he was deeply engaged in the study of oratory, poetry, and every branch of polite literature, he was initiated by his faithful friend Mr Jones in the mysteries of Hutchinsonianism; but Mr Jones was not his preceptor. Indeed that gentleman informs us, that when he first communicated to Mr Horne the novelties with which his own mind was filled, he found his friend very little inclined to confider them; and had the mortification to fee, that he was himself losing ground in Mr Horne's esteem, even for making the attempt to convert him. At this we are not to be much surprifed. Mr Horne, though, by his biographer's account, no deep Newtonian, faw, or thought he faw, the necessity of a vacuum to the posfibility of motion; and as we believe that every man, who knows the meaning of the words motion and vacuum, and whose mind is not biassed in favour of a system, fees the same thing, it was not to be supposed, that a youth of found judgment would hastily relinquish fo natural a notion. By Mr Horne, however, it was at length relinquished. Mr Jones introduced him to Mr George Watson, a fellow of University college, whom he represents as a man of very superior accomplishments; and by Mr Watson Mr Horne was made a Hutchinsonian of such zeal, that at the age of nineteen he implicitly adopted the wild opinion of the author of that fystem, that Newton and Clarke liad formed the defign of bringing the Heathen Jupiter, or Stoical anima mundi, into the place of the God of the universe. With fuch a conviction impressed upon his mind, it is not wonderful that he should endeavour to discredit the fystem of Newton. This he attempted, by publishing a parallel between that system and the Heathen doctrines in the Somnium Scipionis of Cicero. That publication, which was anonymous, we have never feen; but Mr Jones himself admits it to have been exception-

5 B

same opinion, for he never republished it, nor, we believe, replied to the answers which it provoked.

He did not, however, descrt the cause, but published, foon afterwards, a mild and ferious pamphlet, which he called A Fair, Candid, and Impartial State of the Cafe between Sir Isaac Newton and Mr Hutchinson. Even of this pamphlet we have not been able to procure a fight; but Mr Jones affures us, that the author allows to Sir Isaac the great merit of having settled laws and rules in natural philosophy, and of having measured forces as a mathematician with sovereign skill; whilst he claims for Mr Hutchinson the discovery of the true physiological causes, by which, under the power of the Creator, the natural world is moved and directed.

If this be a fair view of the state of the case, it allows to Newton more than ever Newton claimed, or has been claimed for him by his fondest admirers; for the laws and rules, which he fo faithfully followed in the fludy of philosophy, were not fettled by him, but by the illustrious Bacon. With respect to the true causes here mentioned, we have repeatedly had occasion, during the course of this Work, to declare our opinion, that all men are equally ignorant of them, if they be confidered as any thing diffinct from the general laws by which the operations of nature are carried on. To the discovery of other physiological causes, Newton, in his greatest work, made indeed no pretension; but it may be worth while, and can hardly be confidered as a digression, to consider what are the pretensions of Hutchinson, to which Messrs Horne and Jones gave

so decided a preference. Mr Hutchinson himself writes so obscurely, that we dare not venture to translate his language into common English, lest we should undesignedly misrepresent his meaning; but according to Mr Jones, who has fludied his works with care, his diftinguishing doctrine in philosophy is, that "The forces, of which the Newtonians treat, are not the forces of nature; but that the world is carried on by the action of the elements on one another, and all under God." What is here meant by the elements, we are taught by another eminent difciple of that school. "The great agents in nature, which carry on all its operations, are certainly (fays Mr Parkhurst) the fluid of the heavens; or, in other words, the fire at the orb of the fun, the light iffuing from it, and the spirit or gross air constantly supporting, and concurring to the actions of the other two." (See CHERUBIM in this Supplement). Mr Horne adopted this system in preference to the Newtonian; because, says his biographer, "It appeared to him nothing better than raving, to give active powers to matter, supposing it capable of acting where it is not; and to affirm, at the same time, that all matter is inert, that is, inactive; and that the Deity cannot act but where he is present, because his power cannot be but where his substance is."

That much impious arrogance has been betrayed, not by Newtonians only, but by philosophers of every fchool, when treating of the modus operandi of the Deity, we feel not ourselves inclined to controvert; but we never knew a well-informed Newtonian, who spoke of the active powers of matter but in a metaphorical fense; and such language is used, and must be used, by

Horne, able; and the amiable author feems to have been of the the followers of Hutchinson. Mr Jones speaks of the Home action of the elements; and Mr Parkhurst calls the fluid of the heavens, which, according to him, confifts of fire, light, and air, agents; but it would furely be uncandid to accuse these two pious men of animating the elements, though we know that adion and adivity, in the literal fense of the words, can be predicated only of living beings. With respect to giving active powers to matter, therefore, the followers of Hutchinson rave just as much as those of Newton; and we see not the raving of either in any other light than as the necessary

consequence of the poverty of language.

But the Newtonian makes matter act upon matter at a distance! No; the genuine Newtonian does not make matter all (in the proper fense of the word) at all; but he believes, that God has so constituted matter, that the motions of different masses of it are affected by each other at a distance: and the Hutchinsonian holds the very fame thing. As this celeftial fluid of Mr Parkhurst's confists partly of air, we know, by the test of experiment, that it is elastic. The particles of which it is composed are therefore distant from each other; and yet they resist compression. How does the Hutchinsonian account for this fact? Perhaps he will fay, that as matter is in itself equally indifferent to motion and rest, God has so constituted the particles of this fluid, that though they possess no innate power or activity of their own, they are affected by each other at a distance, in consequence of his fiat at the creation. This we believe to be the only folution of the difficulty which can be given by man; but it is the very answer given by the Newtonians to those who object to them the abfurdity of supposing matter to be affected by mat-That the motions of the heavenly ter at a distance. bodies are affected by the presence of each other is a fact, fay they, which appears incontrovertible. "We have afcertained with precision the laws by which these motions are regulated: and without troubling ourfelves with the true physiological causes, have demonstrated the agreement of the phenomena with the laws. The interpolition of this celestial fluid removes not a fingle difficulty with which our doctrine is supposed to be clogged. To have recourse to it can therefore serve no purpofe, even were the phenomena confistent with the nature of an elastic sluid considered as a physical cause; but this is not the case. It is demonstrable (see Astro-NOMY and DYNAMICS in this Suppl.), that the motions of the heavenly bodies are not confishent with the mechanism of an elastic sluid, considered as the cause of these motions; and therefore, whether there be fuch a fluid or not diffused through the solar system, we cannot allow that it is the great agent in nature by which all its operations are carried on."

Such might be the reasoning of a well informed Newtonian in this controverfy; and it appears so conclusive against the objections of Hutchinson to the Newtonian forces, as well as against the agents which he has substituted in their stead, that some of our readers may be disposed to call in question the soundness of that man's understanding who could become a Hutchinsonian so zealous as Mr Horne. But to these gentlemen we beg leave to reply, that the foundest and most upright mind is not proof against the influence of a system, especially if that fystem has novelty to recommend it, and at the same time confists of parts, of which, when taken sepaHutchinson when adopted by Mr Horne. It was then but very little known; it could be fludied only through the medium of Hebrew literature, not generally cultivated; and that literature, to the cultivation of which Mr Hutchirson had given a new and a better turn, is in itself of the utmost importance. Let it be observed, too, that the Hutchinsonians have, for the most part, been men of devout minds, zealous in the cause of Christianity, and untainted by Arianism, Socinianism, and the other herefies which have fo often divided the church of Christ:-and when all these circumstances are taken into confideration, it will not be deemed a proof of any defect in Mr Horne's understanding, that in early life he adopted the whole of a fystem, of which fome of the parts contain fo much that is good; especially when it is remembered, that at first view the agency of the celeftial fluid appears fo plaufible, that for a time it feems to have imposed upon the mind of New-

ton himself. But the truth is, that Mr Horne was at no period of his life a thorough paced Hutchinsonian. It is confessed by Mr Jones, that "Mr Hutchinson and his admirers laid too great a stress on the evidence of Hebrew etymology; and that some of them carried the matter fo far, as to adopt a mode of speaking, which had a nearer resemblance to cant and jargon than to found fense and sober learning. Of this (continues he) Mr Horne was very foon aware; and he was in fo little danger of following the example, that he used to display the foibles of such persons with that mirth and good humour," which he possessed in a more exquisite degree than most men. This seems to be complete evidence that he was never a friend to the etymological part of the fystem; and the present writer can attest, that, in the year 1786, he feemed by his converfation to have lost much of his conviction of the agency of the celeftial fluid. He continued, indeed, to fludy the Hebrew Scriptures on the plan of Mr Hutchinson, unincumbered with the Masoretic points, or with rabbinical interpretations; and the fruits of his studies are in the hands of the religious public, in works which, by that public, will be esteemed as long as their language is understood.

Hitherto Mr Horne was a layman, but he interest. ed himself in every thing connected with religion, as much as the most zealous dignitary of the church; and considering the naturalization of the Jews as a measure at least indecent in a Christian country, he published, in an evening paper, a feries of letters on that subject, both when the Jew bill was depending, and after it had paffed the house. The letters were anonymous; but they attracted much notice, and many groundless conjectures were made respecting their author. To the real author, the measure which they opposed was so very obnoxious, that he refused to dine at the table of a friend, only because the son in-law of Mr Pelham was to be there. And he was not much more friendly to the marriage act than to the Jew bill. If he confidered the one as difgraceful to religion, he probably thought that the other, with its numerous clauses, might

be made a fnare for virtue.

The time now approached when he was to take holy orders, which to him was a very ferious affair; and when he gave an account of his ordination to an inti-

Fine. rately, many are valuable. Such was the fyshem of mate friend, he concluded the letter with the following Horre, reflections, which, even in an abstract like this, it would

be unpardonable to omit:

"May he, who ordered Peter three times to feed his lambs, give me grace, knowledge, and skill, to watch and attend to the flock which he purchased upon the cross, and to give rest to those who are under the burden of fin and forrow. It hath pleased God to call me to the ministry in very troublesome times indeed, when a lion and a bear have broken into the fold, and are making havoc among the sheep. With a firm, though humble confidence, do I purpose to go forth; not in my own strength, but in the strength of the Lord God; and may he prosper the work of my hands!" This was in the year 1753, when the pious author was hardly 23 years of age; and he had not been many months in orders, when one of the most celebrated preachers in the metropolis pronounced, that "George Horne was, without exception, the best preacher in England."

In the year 1756, he was again involved in controversy. A pamphlet had been published at Oxford, supposed by Mr Kennicot, who afterwards gained such fame as a collator of Hebrew manuscripts, entitled A Word to the Hutchinfonians, in which Mr Horne was perfonally ftruck at. To this work our author replied in a small tract, called An Apology for certain Gentlemen in the University of Oxford, Aspersed in a late Anonymous Pamphlet; and whatever may be thought of the question at iffue, all men must admire the temper with which the apologist conducted himself under very great

provocation.

But it was not about Hutchinsonianism alone that these two illustrious men were doomed to differ. Mr Horne took a decided part against Mr Kennicott's proposal for collating the text of the Hebrew bible, with fuch manuscripts as could be found, for the purpose of reforming the text, and preparing it for a new translation into the English language; and in the year 1760, he published A View of Mr Kennicott's Method of Correling the Hebrew Text, with three Queries formed thereon, and humbly fubmitted to the Christian world. That his alarm was on this occasion too great, experience has shewn; but that it was not groundless, is evident from the View, in which the reader will find above 20 inftances from Mr Kennicott's differtations (fee KENNICOTT, Encycl.), to shew what an inundation of licentious criticism was breaking in upon the facred text. Indeed there is reason to believe, that this tract, together with another on the same side of the question by Dr Rutherforth of Cambridge, contributed to repress the collator's rashness, and to make the Bible of Dr Kennicott the valuable work which we find it. Be this as it may, such was the moderation of the Drs Kennicott and Horne, that though their acquaintance commenced in hostility, they at length contracted for each other a friendship, which lasted to the end of their lives, and still subsists between their fami-

In what year Mr Horne was admitted to the degree of D. D. and when he was chosen president of his college, Mr Jones has not informed us; but, if our memory does not decrive us, he had obtained both these preferments when, in the year 1772, he gave to the public a fmall work, 8vo, intitled Confiderations on the Horne. Life and Death of St John the Baptist. This tract was the substance of a course of sermons, which he had many years before, in conformity to an established custom at Magdalen College, preached before the university of Oxford. Mr Jones, speaking of it, says, that "he is persuaded, there was no other man of his time, whose fancy as a writer was bright enough, whose skill as an interpreter was deep enough, and whose heart as a moralist was pure enough, to have made him the author of that little work." By most readers this strain of panegyric will be thought extravagant, and of course it will defeat its own purpose; but the work is certainly a work of merit.

In the year 1776, when the author was vice-chancellor, was published, in two volumes 4to, Dr Horne's Commentary on the Pfalms. It is a work of which very different opinions have been formed, though it was the result of the labour of twenty years. That it will always be a favourite companion of the devout Christian, we are as much inclined to believe as Mr Jones; but we cannot, without belying our own judgment, fay that it appears to us calculated to produce much general good in an age like the present. Granting it to be true, which we believe will not be granted without some exceptions, that Clarke, and Hoadley, and Hare, and Middleton, and Warburton, and SHERLOCK, and SOUTH, and WIL-LIAM LAW, and Edmund Law, had turned the public attention, of which they had got the entire command, too much to the letter of the bible to the neglect of the spirit of it; should not Dr Horne, after the example of St Paul, have let in the light gradually upon fuch weak organs as those of the public thus diseased, rather than pour it upon them at once in a flood of splendor. The apossle "fed his Corinthian converts with milk and not with meat," when he found them unable to bear the latter food; and there is reason to suspect that the earnal followers of Warburton, and Sherlock, and South, were unable to bear, at once, such strong meat, as that which makes the fifteenth pfalm a portrait of our Saviour. Indeed, we think it not improbable that the mind of Sherlock would have recoiled with horror from the very conception of the possibility of Jesus Christ " fwearing to his neighbour and disappointing him," though that conception must have passed through a mind which was certainly as pure as his. The commentary, however, though truth thus compels us to fay that, in our opinion, it is far from perfect, is certainly a work of great learning, great genius, and fervent piety, and fuch as the devout Christian will peruse again and again with much advantage.

Dr Horne's next work was of a different kind, and, we think, of a superior order. In the year 1776 was published a letter of Dr Adam Smith's, giving an account of the death of Mr David Hume. The object of the author was to shew that Mr Hume, notwithstanding his feeptical principles, had died with the utmost composure, and that in his life as well as at his death he had conducted himself as became one of the wifest and best men that ever existed. The letter is very much laboured, and yet does no honour either to the author or his friend. It could not represent Mr Hume as supporting himself under the gradual decay of Nature with the hopes of a happy immortality; but it might have reprefented him as taking refuge, with other infidels, in the eternal steep of death. This, though but a gloomy prospect, would

not have been childish; but the hero of the tale is ex. Horne, hibited as talking like a school boy of his conferences with Charon, and his reluctance to go into the Stygian ferry-boat, and as confoling himfelf with the thought of leaving all his friends, and his brother's family in particular, in great prosperity!!! The absurdities of this letter did not escape the watchful and penetrating eye of Dr Horne; and as he could not mistake its object, he held it up to the contempt and fcorn of the religious world in A Letter to Adam Smith, L. L. D. on the Life, Death, and Philosophy of his Friend David Hume, Esq; by one of the People called Christians. The reafoning of this little tract is clear and conclusive, while its keen, though good humoured wit is inimitable; and it was, some years afterwards, followed by a series of Letters on Infidelity, composed on the same plan, and with much of the same spirit. This finall volume, to the fecond edition of which the letter to Dr Smith was prefixed, is better calculated than almost any other with which we are acquainted, to guard the minds of youth against the infidious strokes of infidel ridicule, the only dangerous weapon which infidelity has to wield.

When the letters on infidelity were published, their author had for some time been Dean of Canterbury, where he was beloved by the chapter and almost adored by the citizens. He was a very frequent preacher in the cathedral and metropolitical church, where the writer of this short sketch has listened to him with delight, and feen thousands of people of very various deferiptions hang with rapture on his lips. As a preacher indeed he excelled; and notwithstanding the shortness of his fight, which deprived him of fome of the graces of a pulpit orator, fuch were the excellence of his matter, the simple elegance of his style, and the sweetness of his voice, that, when at the primary visitation of the prefent archbishop, he preached his admirable sermon on the Duty of Contending for the Faith, the attention of more than 2000 people was fo completely fixed, that the smallest noise was not to be heard through the whole crowded choir. Of the importance of preaching, and of the proper mode of performing that duty, he had very just notions; and though he never had himself a parochial cure of fouls, it was the defire and pleafure of his life to make himself useful in the pulpit wherever he was, whether in town or in the most obscure corner of the country. Four or five volumes of his fermons have been published since his death.

In the year 1787 he published, under the name of an undergraduate of the univerfity of Oxford, a letter to Dr Priefley, in which he made that oracle of Socinianism almost as ridiculous as, in the letter to Dr Smith, he had formerly made the hero of modern feepticism.

The merits of Dr Horne, which had made him prefident of Magdalen College, a king's chaplain, and dean of Canterbury, raifed him, we think in the year 1790, to the fee of Norwich; and he had foon an opportunity of shewing that he had not lost fight of his spiritual character in the splendor of the peer of parliament. The Scotch Episcopalians had for some time been soliciting the legislature to repeal certain penal laws of uncommon feverity, under which they had groaned for upwards of forty years; but they found it a work of no little difficulty to make the equity of their claim ge-Scotch nerally understood*. In removing this difficulty no man Episcopawas more affifting to them than the Dean of Canter-this Supple

bury, ment.

were well known; and he continued his affistance after he was bishop of Norwich. Indeed the whole bench shewed, on this occasion, a zeal for the interests of true religion every way becoming their character of Christian bishops; and after Dr Horne was removed to a better world, the Scotch Episcopalians found among his surviving brethren friends as zealous and active as he.

Dr Horne, though a very handsome man, was not naturally of a strong constitution; and from the disadvantage of being uncommonly near fighted, he had not been able to increase its strength by the practice of any athletic exercise. The only amusement in which he took delight was agreeable conversation; and his life was therefore what is called fedentary. The confequence of this was, that the infirmities of age came fast upon him; and when the delign was formed of making him a bishop, he felt himself little inclined to undertake the charge of fo weighty an office. He was, however, prevailed upon to accept of the fee of Norwich; but he enjoyed his new dignity for a very short period, if he can with truth be said to have enjoyed it at all. His health declined rapidly; and, in the autumn of 1791, he fuffered, while on the road from Norwich to Bath, a paralytic stroke, the effects of which he never reco-He lingered a month or two, with fuch apparent changes in the state of his health as sometimes gave delusive hopes to his family, till the 17th of January 1792, when he died in the 62d year of his age, with those hopes which can be excited only by the consciousness of a well spent life, and by a firm trust in the pro-

mifes of the gospel.

In this short sketch of the life of bishop Horne we have taken the liberty to express our diffent from some of his opinions, and to flate the reasons on which that diffent rests. By himself we know that this part of our conduct would have been applauded; but it is possible that by some of his friends it may be deemed difrespectful to his memory. To these gentlemen we beg leave to observe, that if Johnson made the praise of Kyrl, Pope's man of Rofs, really more folid by making it more credible, it will be difficult to perfuade us that we have done any injury to Dr Horne's fame by avoiding the extravagant panegyric of those who seem to have confidered him as a man exempted from error. He was first induced to favour the Hutchinsonians because he thought he perceived danger to religion in the Newtonian doctrines of attraction and repulsion; and we very readily admit that many Newtonians, not understanding the doctrines of their master, have expressed themselves in such a manner as could not render a religious man partial to their fystem. But from the dangers of miftake no fystem, whether religious or philosophical, was ever free; and the atheitical purposes which the agency of ethers and celestial fluids has lately been made to serve, must induce every man of piety to pause before he admit fuch agency. Dr Horne lived to witness some of its pernicious effects; and we have reason to believe that they made a due impression on his mind; but he spent his latter years, as indeed he had spent the greater part of his life, in nobler pursuits than the study of human science; he spent them in the proper employments of a Christian, a clergyman, and a bishop. His faith was founded on a rock; and it was that genuine faith which worketh by love; for though his preferments is hoven, let one person take hold of him by the nostril

He c. bury, to whom their religious and political principles were rich, his charity kept pace with them; and it Hotograhas been proved that, notwithstanding his proper economy, he hoarded not one shilling of his annual income. This was an elevation of character above all literary, above all philosophic fame. 'I'he author of this article had the honour to be known to Dr Horne, to enjoy, if he miltook not, a share in his friendship, and to correspond with him regularly for many years; and there is not one of his rational admirers who more fully admits the truth of the character given of him by Dr Thurlow late bishop of Durham when succeeding him in the office of proctor in the University. " As to the last proctor (faid he) I shall speak of him but in few words, for the truth of which I can appeal to all that are here present. If ever virtue itself was visible and dwelt upon earth, it was in the person who this day lays down his office."

Soon after he was advanced to the prefidentship of Magdalen college, this great and good man married the only daughter of Philip Burton, Esq; a gentleman of confiderable fortune. By this lady he had three daughters, of whom the eldest was married to a clergyman a short time before the death of her father, and the two younger were, in 1796, refiding with Mrs Horne in Hertfordshire.

HOROGRAPHY, the art of making or construct. ing dials; called also dialling, horologiography, gnomonica, sciatherica, photosciatherica, &c.

HOROPTER, in optics, is a right line drawn through the point where the two optic axes meet, parallel to that which joins the centres of the two eyes, or the two pupils.

HORSE-SHOE, in fortification, is a work fometimes of a round, sometimes of an oval figure, inclosed with a parapet, raifed in the ditch of a marshy place, or in low grounds; fometimes also to cover a gate; or to serve as a lodgment for foldiers, to prevent furprifes, or relieve an over tedious defence.

HOVEN is a word of the same import with raised, swelled, tumefied. It is particularly applied to black cattle and sheep, when from eating too voraciously of clover, or any other succulent food, they become swollen. Such cattle are, in the language of the farmer, called

HOVEN. Cattle; and the beaft, whether bullock or sheep, which is hoven, when left without relief, dies in half an hour. The cause of the disease is the extraquantity of air taken down with that kind of food, which, in its passage from the paunch upwards, forces the broad leaves of the clover before it, till they close np the passage at the entrance of the paunch, and prevent the wind from going upwards in its regular course. The usual method of relief is to stab the animal in the paunch; an operation which is always dangerous, and has often proved fatal. It was therefore with good reason that the Society for the Encouragement of Arts, Manufactures, and Commerce, voted a bounty of fifty guineas to Mr Richard Eager of Graffham farm, near Guildford, for making public a very simple method practifed by him for the cure of hoven-cattle. It is this; "let the grazier or farmer have always ready smooth knobs of wood, of different fizes, fixed to the end of a flexible cane, which for oxen should be at least fix feet long, and for sheep three feet. When a beast

stion.

Houghton, and one horn; let another hold his tongue fast in one hand, putting the cane down his throat with the other. Be careful not to let the animal get the knob of the cane between his grinders: observe also to put the cane far enough down; the whole length will not injure. You will find the obstacle at the entrance of the paunch: push the cane hard, and when you perceive a smell to come from the paunch, and the animal's body to fink, the cure is performed, and Nature will act for itself."

This method, we doubt not, will prove successful; but might not the purpose be as well, if not better, effected, by using, instead of the cane and knob, a piece of thick stiff rope, which, in many places of Scotland, is employed to force down turnips or potatoes when they

flick in the throat of a bullock?

HOUGHTON (---) is a man to whom the science of geography is so much indebted, that we are almost ashamed to confess that we know not his Christian name, the place where he was born, or the age at which he died. He had been a captain in the 69th regiment, and in the year 1779 had acted under General Rooke as fort major in the island of Goree. Hearing, fome time in the year 1789, or perhaps earlier, that the African affociation wished to penetrate to the Niger by the way of Gambia, he expressed his willingness to undertake the execution of their plan. For this task he was peculiarly fitted. A natural intrepidity of character, which feemed inaccessible to fear, and an easy flow of constitutional good humour, which even the roughest accidents of life were not able to fubdue, formed him for exploring the country of relentless savages; whilst the darkness of his complexion was such, that he scarcely differed in appearance from the Moors of Barbary, whose dress in travelling he intended to assume.

His instructions from the affociation were, to ascertain the course, and, if possible, the rise and termination of the Niger; and after vifiting the cities of Tombuc-Too and Houssa (fee these articles in this Supplement), to return by the way of the defart, or by any other route which the circumstances of his situation at the

time might recommend to his choice.

Having left England on the 16th of October 1790, he arrived at the entrance of the Gambia on the 10th of November, and was kindly received by the king of Barra, who remembered the vifit which the Major had of the Afri-formerly paid him from the island of Goree; and who can Affocia- now, in return for a small present of the value of 208. cheerfully tendered protection and affiftance as far as his dominion or influence extended.

> An offer from the master of an Euglish vessel employed in the trade of the river, enabled the Major, and the interpreter he had engaged on the coast, to proceed to Junkiconda; where he purchased from the natives a horse and five affes, and prepared to pass with the merchandife which constituted his travelling fund, to Medina, the capital of the small kingdom of Woolli.

> Fortunately for him, a few words, accidentally dropped by a negro woman in the Mandingo language, of which he had hastily acquired a superficial knowledge, excited fuspicions of danger; and gave him intimation of a conspiracy which the negro mistresses of the traders, who feared that the Major's expedition portended the ruin of their commerce, had formed against his life. Afraid, therefore, of travelling by the customary route, -he availed himself of the opportunity which the dry sea-

fon and the tide of ebb afforded of fwimming his horse Houghton and his affes across the stream; and having by those means avoided the parties who were fent for his destruction, he proceeded with much difficulty on the fouthern fide of the river, to that district of Cantor which is op. posite to the kingdom of Woolli. There he repassed the Gambia, and fent a messenger to inform the king of his arrival, and to requelt a guard for his protection.

An efcort, commanded by the king's fon, was immediately dispatched; and the Major, whose intended prefent had been announced, was kindly received, and hof-

pitably entertained at Medina.

The town is fituated at the distance of about 900 miles by water from the entrance of the Gambia; and the country adjacent abounds in corn and cattle, and, generally speaking, in all things that are requisite for the support, or essential to the comfort of life. Two different fects of religion diftinguish rather than divide the people; the one is composed of the professors of the Mahomedan faith, who are called Bushreens; the other, and, it is faid, the more numerous, confifts of those who, denying the mission of the prophet, avow themselves deits, and from their cultom of drinking with freedom the liquors of which he prohibited the use, are denominated Sonikees or drinking men.

In a letter from Major Houghton to his wife, which a feaman preferved from the wreck of a veffel in which the dispatches to the society were lost, the Major indulged the reflections that naturally arose from his past and present situations. A bilious fever had attacked

him foon after his arrival in the Gambia; but his health was now unimpared—a conspiracy had assailed his life; but the danger was paffed-the journey from Junkiconda had exposed him to innumerable hardships; but he was now in possession of every gratification which the kindness of the king or the hospitality of the people could enable him to enjoy. Delighted with the healthiness of the country, the abundance of the game, the security with which he made his excursions on horseback, and above all, with the advantages that would attend the erection of a fort on the falubrious and beautiful hill of Fatetenda, where the English once had a factory, he expresses his earnest hope that his wife will hereafter accompany him to a place in which an income of ten

pounds a year will support them in affluence; and that

the will participate with him in the pleasure of rapidly

acquiring that vast wealth which he imagines its commerce will afford.

While, in this manner, he indulged the dream of future prosperity, and with still more ample satisfaction contemplated the eclat of the discoveries for which he was preparing, but in the purfuit of which he was retarded by the absence of the native merchant, for whose company he had engaged, he found himself suddenly involved in unexpected and irrefiftible misfortune. A fire, the progress of which was accelerated by the bamboo roofs of the buildings, confumed with fuch rapidity the house in which he lived, and with it the greatest part of Medina, that several of the articles of merchandize, to which he trufted for the expences of his journey, were deftroyed; and to add to his affliction, his faithless interpreter, who had made an ineffectual attempt on his goods, disappeared with his horse and three of his affes; a trade gun which he had purchased on the river soon afterwards burft in his hands,

How ton and wounded him in the face and arm: and though the hospitable kindness of the people of the neighbouring town of Barraconda, who cheerfully opened their houses to more than a thousand families, whose tenements the flames had confumed, was anxiously exerted for his relief; yet the lofs of his goods, and the confequent diminution of his travelling fund, were evils which no kindness could remove.

It was in this fituation that, wearied with the fruitless hope of the return of the native trader, with whom he had contracted for his journey, he resolved to avail himself of the company of another slave merchant, who was lately arrived from the fouth, and was now on his way to his farm on the frontier of the kingdom of Bambouk. Accordingly, on the evening of the 8th of May, he proceeded by moon light and on foot, with his two affes, which the fervants of the flave merchant offered to drive with their own, and which carried the wreck of his fortune; and journeying by a north east course, arrived on the fifth day at the uninhabited frontier which feparates the kingdoms of Woolli and Bon-

He had now passed the former limit of European discovery; and while he remarked with pleasure the numerous and extensive population of this unvisited country, he observed, that the long black hair and copper complexion of the inhabitants announced their Arab original. They are a branch of that numerous tribe which, under the appellation of Foolies, have overfpread a considerable part of Senegambia; and their religious distinctions are similar to those which prevailin the kingdom of Woolli.

A journey of 150 miles, which was often interrupted by the engagements of his companion, who traded in every town, conducted him to the banks of the Falemé, the fouth-western boundary of the kingdom of Bambouk. Its stream was exhausted by the advanced state of the dry season, and its bed exhibited an appearance of flate intermixed with gravel.

Bambouk is inhabited by a nation, whose woolly hair and fable complexions befpeak them of the negro race, but whose character feems to be varied in proportion as the country rifes from the plains of its western division to the highlands of the east. Diftinguished into fects, like the people of Woolli and Bondou, by the different tenets of Mahomedans and Deists, they are equally at peace with each other, and mutually tolerate the respective opinions they condemn.

Agriculture and pasturage, as in the negro states on the coast of the Atlantic, are their chief occupations; but the progrefs which they have made in the manufacturing arts, is fuch as enables them to fmelt their iron ore, and to furnish the feveral instruments of hufbandry and war. Cloth of cotton, on the other hand, which in this part of Africa feems to be the universal wear, they appear to weave by a difficult and laborious process; and to these two circumstances it is probably owing, that with them the measure of value is not, as on the coast, a bar of iron, but a piece of cloth.

The common vegetable food of the inhabitants appears to confift of rice; their animal, of beef or mutton. A liquor, prepared from fermented honey, supplies the want of wine, and furnishes the means of those teflive entertainments that conflitute the luxury of the court of Bambouk.

On the Major's arrival at the banks of the river Fa. II) ughtonlemé, he found that the war which had lately subfifted between the kings of Bondou and Bambouk was terminated by the cession to the former of the conquests he had made in the low land part of the dominions of the latter; and that the king of Bondou had taken up his refidence in the territory which he had thus obtain-

The Major hastened to pay his refrects to the vietorious prince, and to offer a fimilar prefent to that which the kings of Barra and Woolli had cheerfully accepted; but to his great disappointment an ungracious reception, a fullen permission to leave the present, and a stein command to repair to the frontier town from which he came, were followed by an intimation that he should hear again from the king. Accordingly, on the next day, the king's fon, accompanied by an armed attendance, entered the house in which the Major had taken up his temporary dwelling, and demanded a fight of all the articles he had brought. Fromthese the prince scheeted whatever commodities were best calculated to gratify his avarice, or please his eye; and to the Major's great disappointment, took from him the blue coat in which he hoped to make his appearance on the day of his introduction to the Sultan of Tombuctoo. Happily, however, a variety of articles were fuccessfully concealed, and others of inferior value were not confidered as sufficiently attractive.

The Major now waited with impatience for the performance of the promise which the slave merchant, with whom he had travelled from the Gambia, had made of proceeding with him to Tombuctoo; but as the merchant was obliged to spend a few days at his rice farm on the banks of the Falemé, the Major accepted an invitation to the hospitality of his roof. There he obferved, with extreme regret, that the apprehension of a scarcity of grain had alarmed his friend; and that, dreading the confequences of leaving his family in fo perilous a feafon to the chances of the market, he had determined on collecting, before his departure, a fufficient supply for their support. This argument for delay was too forcible to be opposed; and therefore the Major resolved to employ the interval in visiting the king of Bambouk, who refided in the town of Ferbanna, on the eastern fide of the Serra Coles, or river of Gold. Unfortunately, however, by a mistake of his guide, he lost his way in one of the vast woods of the country; and as the rainy feafon, which commenced with the new moon on the 4th of July, and was introduced with a westerly wind, was now set in, the ground on which he passed the night was deluged with rain, while all the sky exhibited that continual blaze of lightning, which in those latitudes often accompanies the tornado. Distressed by the fever, which began to affail him, the Major continued his route at the break of day, and waded with difficulty through the river Serra Coles, which was fwelled by the floods, and on the banks of which the alligators were basking in the temporary fun-shine.

Scarcely had he reached Ferbanna when his fever rose to a height that rendered him delirious; but the firength of his constitution, and the kindness of the negro family to which his guide had conducted him, furmounted the dangerous difease; and in the friendly reception which was given him by the king of Bambouk,

Houghton. he foon forgot the hardships of his journey. The king but he was shewn at a distance the spot in the woods House. informed him, that the loffes he had lately fustained in to which his body was dragged, and where it was left the contest with the armies of Bondou, arose from his a prey to corruption. having exhausted his ammunition; for, as the French traders, who formerly supplied his troops, had aban- a man whose travels enlarged the limits of European doned the fort of St Joseph, and, either from the dry- discovery, and whose accounts of the places which he visitness of the last season, or from other causes, had desert- ed were strongly confirmed by the intelligence which the ed the navigation of the upper part of the Senegal, he

had no means of replenishing his flores; whereas his enemy, the king of Bondon, continued to receive from the British, through the channel of his agents on the Gambia, a constant and adequate supply. Major Houghton availed himself of the opportunity

which this conversation afforded, to suggest to the king the advantage of encouraging the British to open a trade by the way of his dominions to the popu-

lous cities on the banks of the Niger.

Such was the state of the negociation, when all business was suspended by the arrival of the annual presents of Mead, which the people of Bambouk, at that feafon of the year, are accustomed to fend to their king; and which are always followed by an intemperate feitival of

feveral successive days.

In the interim, the Major received, and gladly accepted, the proposal of an old and respectable merchant of Bambouk; who offered to conduct him on horseback to Tombuctoo, and to attend him back to the Gambia. A premium of L.125, to be paid on the Major's return to the British factory at Junkiconda, was fixed by agreement as the merchant's future re-It was further determined, that the Major should be surnished with a horse in exchange for his two affes; and should convert into gold dust, as the most portable fund, the scanty remains of the goods he

had brought from Great Britain.

This plan was much approved by the king, to whom the merchant was perfonally known; and who gave to the Major at parting, as a mark of his efteem, and a pledge of his future friendship, a present of a purse of gold. With an account of these preparations the Major closed his last dispatch, of the 24th July 1791; and the African affociation entertained for fome time fanguine hopes of his reaching Tombuctoo. Alas! these hopes were blafted. Mr Park, who fucceeded him in the arduous talk of exploring that favage country, learned, that having reached JARRA (See that article in this Supplement), he there met with some Moors who were travelling to Tifheet (a place by the falt pits in the Great Defart, ten days journey to the northward) to purchase salt; and that the Major, at the expence of some tobacco and a musket, engaged them to convey him thither. It is impossible (fays Mr Park) to form any other opinion on this determination, than that the Moors intentionally deceived him with a view to rob, and leave him in the Defart. At the end of two days he suspected their treachery, and insisted on returning to Jarra. Finding him perfift in this determination, the Moors robbed him of every thing which he possessed, and went off with their camels. Being thus deferted, he returned to a watering place, in possession of the Moors, called Farra; and being by these unfeeling wretches refused food, which he had not tafted for some days, he funk at last under his misfortunes. Whether he actually died of hunger, or was murdered outright by the favage Mahometans, Mr Park could not learn;

Thus perished, in the prime of life, Major Houghton, British conful at Tunis collected from the Barbary

merchants.

HOUSSA, the capital of an African empire, on the banks of the Niger, is a city which has excited much curiofity among men of science, fince it was first mentioned to a committee of the African Affociation about the year 1790. The perfon from whom they received their information was an Arab, of the name of Shabeni; who faid that the population of Houssa, where he had refided two years, was equalled only (fo far as his knowledge extended) by that of London and Cairo: and, in his rude unlettered way, he described the government as monarchical, yet not unlimited; its justice as severe, but directed by written laws; and the rights of landed property as guarded by the inflitutions of certain hereditary officers, whose functions appear to be fimilar to those of the Canongoes of Hindostan (See CANONGOES, in this Suppl.); and whose important and complicated duties imply an unufual degree of civilization and refinement. For the probity of the merchants of Houssa, the Arab expressed the highest respect; but remarked, with indignation, that the women were admitted to fociety, and that the honour of the husband was often infecure. Of their written alphabet he knew no more, than that it is perfectly different from the Arabic and the Hebrew characters; but he represented the art of writing as common in Houssa. And when he described the manner in which their pottery is made, he gave, unknowingly to himself, a representation of the antient Grecian wheel. In passing to Houssa from Tombuctoo, in which last city he had resided seven years, he found the banks of the Niger more numeroufly peopled than those of the Nite, from Alexandria to Cairo; and his mind was obvioufly impressed with higher ideas of the wealth and grandenr of the empire of Houssa, than of those of any kingdom which he had feen, England alone excepted.

The existence of the city of Houssa, and of the empire thus described by Shabeni, was strongly consirmed by letters which the committee received from his Majefty's confuls at Tunis and Morocco; and it has been put beyond all possibility of doubt by Mr Park, who received from various persons such concurring accounts of it, as could not be the offspring of deliberate falsehood. From a well informed shereoff, who had visited Houssa, and lived fome years at Tombuctoo, he learned, that the former of these cities was the largest that the shereesf had ever feen; and by comparing this man's account of its population with that of various other cities, of which Mr Park had feen one or two, we can hardly estimate the inhabitants of Houssa at a less number than 100,000. Many merchants, with whom our traveller conversed, represented Houssa as larger, and more populous than Tombuctoo, and the trade, police, and government as nearly the fame in both. In that case, the king of Housia and chief officers of state must be Moors, and zealots for the Mahometan religion; but they cannot be fo intolerant as the fovereign of Tom-

How, buctoo, and his ministers; for in Houssa, Mr Park was imagined that men of a different colour were born only Houzou-Hou 1. told that the negroes are in greater proportion to the Moors than in Tombuctoo, and that they have likewife some share in the government. According to accounts derived from Barbary merchants, the people of Honsia have the art of tempering their iron with more than European skill; and their files in particular are much superior to those of Great Britain and France. The confuls at Tunis and Morocco affured the committee of the African Affociation, that at both thefe courts the eunuchs of the feraglio are brought from

To those who may still entertain doubts of so much refinement being to be found in the interior parts of a country, confidered as peculiarly favage, we shall only observe, in the words of the committee of affociation, that it is by no means "impossible that the Carthaginians, who do not appear to have perished with their cities, may have retired to the fouthern parts of Africa; and though loft to the Defart, may have carried with them to the new regions which they occupy, fome portion of those arts and sciences, and of that commercial knowledge, for which the inhabitants of Carthage were once so eminently famed. In Major Rennel's last map of North Africa, Houssa is placed in 16° and about 20' N. I. and 4° 30' E. Long.

HOUZOUANAS are a wandering people, who inhabit that part of Africa, which, in a direction from east to west, extends from Cassraria to the country of the Greater Nimiquas (See NIMIQUAS, in this Suppl.) According to the map prefixed to Vaillant's new travels, the district occupied by the Houzouanas lies between 16° and 29° east longitude. Of its breadth from fouth to north, we are ignorant; but it begins at the 23d parallel, and firetches northward probably a

M. Vaillant is inclined to believe, that the Houzouanas are the original stem of the various nations, inhabiting at present the southern part of Africa, and that from them all the tribes of the eastern and western Hottentots are descended. The people themselves know nothing of their origin; but to the questions that are put to them on the subject, they always reply, that they inhabit the country which was inhabited by their ancestors. At the Cape, M. Vaillant received the following account of them, which, though he does not warrant its authenticity, has much the appearance of being authentic.

When the Europeans first established themselves at the Cape, the Houzouanas inhabited the country of Camdebo, the fnowy mountains, and the district that separates these mountains from Caffraria. neighbours to the colony, in consequence of its extending itself towards them, they at first lived on peaceable terms with the planters; and, as they displayed more intelligence and greater activity than the Hottentots, they were even employed in preference to affift in cultivating the land and in forming the fettlement. This good understanding and harmony were, however, soon inter-rupted by that multitude of lawless banditti sent from Holland to people the country.

Those worthless profligates wished to enjoy the fruits of the land without the trouble of tilling it. Educated, besides, with all the prejudices of the whites, they

SUPPL. VOL. I. Part II.

to be their slaves. They accordingly subjected them to bondage, condemned them to the most laborious services, and repaid those services with harsh and severe treatment. The Houzouanas, incensed at such arbitrary and tyrannical conduct, refused any longer to work for them, and retired to the defiles of their mountains. The planters took up arms and purfued them; they maffacred them without pity, and feized on their cattle and their country. Those who escaped their atrocities betook themselves to slight, and removed to the land which they now occupy; but, on quitting their former possessions, they swore, in their own name and that of their posterity, to exterminate those European monsters, to be revenged against whom they had so many incitements. And thus, if tradition be true, was a peaceful and industrious nation rendered warlike, vindictive, and ferocious.

This hatred has been perpetuated from generation to generation, though the Houzouanas of the prefent day are ignorant of the original cause of it. Bred up with an invincible averfion to the planters, they know only that they are animated to plunder and destroy them; but it is only by a vague fentiment of deteftation, with the fource of which they are unacquainted; and which, though it renders them cruel towards the planters, does not prevent them from being good, kind, and humane,

towards each other.

The Houzouanas, being known only by their incurfions and plundering, are in the colonies often confounded with the Boshmen, and distinguished by the same appellation. Sometimes, however, from their tawny colour, they are called Chinese Hottentots; and, by means of this double denomination, ill-informed travellers may eafily be led into an error, of which the confequence must be, that their narratives will be replete

with abfurdity and falsehoods.

Their real name, and the only one which they give themselves, is that of Houzouana; and they have nothing in common with the Boshmen, who are not a diffinct people, but a mere collection of fugitives and free-booters. The Houzouanas form no alliances but among themselves. Being almost always at war with the furrounding nations, they never mix with them; and, if they confent at any time to admit a stranger into their hordes, it is only after a long acquaintance. a fort of apprenticeship, during which he has given proofs of his fidelity, and established his courage. Such indeed are their courage and predatory habits, that they are the dread of all the furrounding tribes; and the Hottentots who accompanied M. Vaillant trembled at the very thought of entering the Houzouana territories. Nay, after they had lived many days among them, and had experienced their fidelity, they continued under the daily apprelienfion of being maffacred by them. Yet one of their own countrymen, who had lived long among the Houzouanas, gave fuch a character of that people as fhould have banished those idle

"The Houzouanas (faid he), are by no means what you suppose them to be, murderers by profession. If they fometimes shed blood, it is not from a thirst of carnage, but to make just reprifals that they take up arms. Attacked and perfecuted by furrounding na-5 C

Houzou- tions, they have found themselves reduced to the neceffity of flying to inacceffible places among the barren mountains, where no other people could exist.

" If they find antelopes and damans to kill; if the nymphs of ants are abundant; or if their good fortune brings them plenty of locusts—they remain within the precincts of their rocks; but if the provisions necessary to subfishence fail, the nations in their neighbourhood must suffer. From the summits of their mountains, they furvey at a distance the countries around; and, if they observe cattle, they make an incursion to carry them off, or flaughter them upon the spot, according to circumstances; but though they rob, they never kill, except to defend their lives, or by way of retaliation to

revenge an ancient injury. "It happens fometimes, however, that after very fatigning expeditions they return without booty; either because the objects of their attack have disappeared, or because they have been repulsed and beaten. In such cases, the women, exasperated by hunger and the lamentation of their children crying for food, become almost furious with passion. Reproaches, infult, and threats, are employed; they wish to separate from such dastardly men, to quit husbands destitute of courage, and to feek others who will be more anxious to procure provision for them and their children. In short, having exhausted whatever rage and despair could fuggest, they pull off their small apron of modesty, and beat their husbands about the head with it till their arms are weary of the exercise.

" Of all the affronts which they can offer, this is the most insulting. Unable to withstand it, the men in their turn become furious. They put on their warcap, a fort of helmet made with the skin that covers the neck of the hyæna, the long hair of which forms a crest that floats over the head, and, setting out like madmen, never return till they have fucceeded in carrying off some cattle.

When they come back, their wives go to meet them, and extol their courage amidst the fondest ca-In a word, nothing is then thought of but mirth and jollity; and, till fimilar scenes are recalled by fimilar wants, past evils are forgotten."

Such was the character given of this formidable people to M. Vaillant at his first interview with them; and during the long excursions which he made in their company, they did not belie it in a fingle instance. In many respects they appeared to resemble the Arabs, who, being also wanderers, and like them brave and addicted to rapine, adhere with unalterable fidelity to their engagements, and defend, even to the last drop of their blood, the traveller who civilly purchases their services, and puts himself under their protection. In our author's opinion, if it be at all practicable to traverse from south to north the whole of Africa, it could only be under the conduct of the Houzouanas; and he really thinks that fifty men of their temperate, brave, and indefatigable nation, would be sufficient to protect an enterprifing European through that long and hazardous journey.

Yet these people, so superior both in body and mind to the other natives of South frica, are but of low stature; and a person five feet four inches in height is accounted among them very tall; but in their little bodies, perfectly well proportioned, are united, with fur-

prifing strength and aguity, a certain air of affurance, House boldness, and haughtiness, which awes the beholder, anas and with which our anthor was greatly pleased. Of all the savage races, he saw none that appeared to be endowed with fo active a mind, and fo hardy a confli-

Their head, though it exhibits the principal characteristics of that of the Hottentot, is, however, rounder towards the chin. They are also not so black in complexion; but have the lead colour of the Malays, diftinguished at the Cape by the name of bouguinée. Their hair, more woolly, is fo flort that he imagined at first their heads to have been shaved. The nose too is still flatter than that of the Hottentots; or, rather, they feem altogether destitute of a nose; what they have confifting only of two broad noffrils which project at most but five or six lines. From this confirmation of the nose, a Houzouana, when seen in profile, is the reverse of handsome, and considerably resembles an ape. When beheld in front, he prefents, on the first view, an extraordinary appearance, as half the face feems to be forehead. The features, however, are fo expressive, and the eyes so large and lively, that, notwithstanding this singularity of look, the countenance is tolerably agreeable.

As the heat of the climate in which he lives renders clothing unnecessary, he continues during the whole year almost entirely naked, having no other covering than a very small jackal skin fastened round his loins by two thongs, the extremities of which hang down to his Hardened by this constant habit of nakedness, he becomes fo infensible to the variations of the atmofphere, that when he removes from the burning fands of the level country to the fnow and hoar-frost of his mountains, he feems indifferent to and not even to feel the cold.

His hut in nowife refembles that of the Hottentot. It appears as if cut vertically through the middle; fo that the hut of a Hottentot would make two of those of the Houzouanas. During their emigrations, they leave them standing, in order that, if any other horde of the same nation pass that way, they may make use of them. When on a journey, they have nothing to repose on but a mat suspended from two slicks, and placed in an inclined position. They often even sleep on the bare ground. A projecting rock is then fufficient to shelter them; for every thing is suited to a people whose constitutions are proof against the severest fatigue. If, however, they stop anywhere to sojourn for a while, and find materials proper for constructing huts, they then form a kraal; but they abandon it on their departure, as is the cafe with all the huts which they erect.

This cultom of labouring for others of their tribe announces a focial character and a benevolent disposition. They are, indeed, not only affectionate husbands and good fathers, but excellent companions. When they inhabit a kraal, there is no fuch thing among them as private property; whatever they posses is in common. If two hordes of the fame nation meet, the reception is on both fides friendly; they afford each other mutual protection, and confer reciprocal obligations. In short, they treat one another as brethren, though perhaps they are perfect strangers, and have never seen each other before.

fider it as amusement to climb mountains, and the most on a journey, or when they have children too young to elevated peaks; and they conducted M. Vaillant, his follow them, they place them upon their rump. fervants and cattle, over precipices, and through defiles, which he and his Hottentots would have deemed abfolutely impassable. The only arms of this people are bows and arrows, in the use of which they are very expert. The arrows, which are uncommonly short, are carried on the shoulder in a quiver, about eighteen inches in length, and four in diameter, made of the bark of the aloe, and covered with the skin of a large species of lizard, which these wanderers find in all their rivers, particularly on the banks of Orange and Fish-River.

Nocturnal fires are a peculiar language understood and employed by almost all favage nations. None, however, have carried this art fo far as the Houzouanas, because none have so much need of understanding and bringing it to perfection. If it be necessary to announce a defeat or a victory, an arrival or departure, a fuccessful plundering expedition, or the want of affiftance, in a word, any intelligence whatever, they are able, either by the number of their fires or the manner in which they arrange them, to make it known in an instant. They are even so fagacious as to vary their fires from time to time, lest their enemies should become acquainted with their fignals, and treacheroufly employ them in their turn to furprise them.

Our author fays, that he is unacquainted with the principles of these figuals, invented with so much ingenuity. He did not request information; because he very rationally inferred that his request would not have been granted; but he observed, that three fires kindled at the distance of twenty paces from each other, so as to form an equilateral triangle, were the figual for rally-

Among the physical qualities, which, in M. Vaillant's opinion, prove that the Houzouanas are a diftinct nation, he mentions the enormous natural rump of the women, as a deformity which diffinguishes them from every other people, favage or polished, which he had ever known. "I have several times (says he) had occasion to remark, that, among the female Hottentots in general, as they advance in age, the inferior part of the back fwells out, and acquires a fize which greatly exceeds the proportion it bore in infancy with the other parts of the body. The Houzonana women, having in their figure fome refemblance to the Hottentots, and appearing, therefore, to be of the fame race, one might be induced to believe that their projection behind is only the Hottentot rump more swelled and extended. I observed, however, that among the former this fingularity was an excrescence of flow growth, and in some measure an infirmity of old age; whereas among the latter it is a natural deformity, an original characteristic of their race. The Houzouana mothers wear on their reins, like our miners, a skin which covers this protuberance of the posteriors; but which, being thin and pliable, yields to the quivering of the

Active and nimble by nature, the Houzouanas con-flesh, and becomes agitated in the same manner. When Hungary. faw one of these women run in this manner with a child, about three years of age, that stood erect on its feet at her back, like a foot-boy behind a carriage."

If one half of what our traveller fays of the activity and enterprifing spirit of this singular people be true, might not the African Affociation, now that the Cape is a British province, send a second Houghton, or second Park, to make discoveries in that unexplored country, under the protection of the Houzouanas? We do not indeed think that it would be possible to traverse the whole extent of Africa from fouth to north, but Vaillant penetrated farther in that direction than any one had done before him; and it appears, that with his intrepid Houzouanas he might have penetrated

much farther.

HUNGARY-WATER, is spirit of wine distilled upon rolemary, and which therefore contains its oily and throng feented effence (fee PHARMACY, no 365, Encycl.). To be really good, fays Profesor Beckmann, Hist. of Inthe spirit of wine ought to be very strong, and the rose-ventions. mary fresh; and if that be the case, the leaves are as proper as the flowers, which, according to the prescription of some, should only be taken. It is likewise neceffary that the spirit of wine be distilled several times upon the rolemary; but that process is too troublesome and expensive to admit of this water being disposed of at the low price it is usually fold for; and it is certain, that the greater part of it is nothing else than common brandy, united with the effence of rolemary in the fimplest manner. In general, it is only mixed with a few drops of the oil. For a long time past, this article has been brought to us principally from France, where it is prepared, particularly at Beaucaire, Montpellier, and other places in Languedoc, in which that plant grows in great abundance.

The name Hungary water feems to fignify, that this water, so celebrated for its medicinal virtues, is an Hungarian invention; and we read in many books, that the receipt for preparing it was given to a queen of Hungary by a hermit; or, as others fay, by an angel, who appeared to her in a garden, all entrance to which was thut, in the form of a hermit or a youth. Some call the queen St Isabella; but those who pretend to be best acquainted with the circumftance affirm, that Elizabeth, wife of Charles Robert king of Hungary, and daughter of Uladislaus II. king of Poland, who died in 1380 or 1381, was the inventrels. By often washing with this spirit of rosemary, when in the 70th year of her age, she was cured, as we are told, of the gout and an univerfal lameness; so that she not only lived to pass 80, but became so lively and beautiful, that she was courted by the king of Poland, who was then a widower, and

who wished to make her his second wife.

The Professor justly considers this story as a ridiculous fable (A). "It appears to me (fays he) most pro-5 C 2

"I Elizabeth, queen of Hungary, being very infirm and much troubled with the gout in the 72d year of my

⁽A) It was fift published to the world in 1659 in a posthumous work of John Prevot, who says, that in the beginning of a very old breviary, he faw a remedy for the gout, written by the queen's own hand, in the follow-

Hunter. bable, that the French name l'eau de la reine d'Hongrie, was chosen by those who, in latter times, prepared spirit of rosemary for sale, in order to give greater consequence and credit to their commodity; as various medicines, some years ago, were extolled in the gazettes under the title of Pompadour, though the celebrated lady, from whose name they derived their importance, certainly neither ever faw them nor used them."

HUNTER (John), the celebrated furgeon, was the youngest child of John Hunter of Kilbride, in the county of Lanark. He was born on the 14th of July 1728, at Long Calderwood, a fmall estate belonging to the family; and losing his father when he was about ten years of age, he was, perhaps, too much indulged by his mother. One confequence of this was, that at the grammar-school he made no progress in learning; and he may be faid to have been almost totally illiterate when, in September 1748, he arrived in London. His brother, Dr William Hunter, of whom an account is given in the Encyclopadia, was then the most celebrated teacher of anatomy, and John had expressed a desire to affilt him in his researches. The Doctor, who was very desirous to serve him, and anxious to form some opinion of his talents for anatomy, gave him an arm to diffect for the muscles, with the necessary directions how it was to be done; and he found the performance fuch as greatly exceeded his expectation.

His first essay in anatomy having thus gained him fome credit, Mr Hunter was now employed in a diffection of a more difficult nature; this was an arm in which all the arteries were injected, and these, as well as the muscles, were to be exposed and preserved. The manner in which this was performed, gave Dr Hunter fo much fatisfaction, that he did not scruple to fay, that his brother would become a good anatomist, and that he should not want for employment. From this period we may consider Mr Hunter as having seriously engaged in anatomy; and under the instructions of Dr Hunter, and his affistant Mr Symonds, he had every opportunity of improvement, as all the diffections at this time carried on in London were confined to that

fchool. In the fummer 1749, Mr Chefelden, at the request of Dr Hunter, permitted him to attend at Chelsea Hospital; and he there learned the first rudiments of sur-

The following winter he was fo far advanced in the knowledge of human anatomy, as to instruct the pupils in diffection, to whom Dr Hunter had very little time to pay attention. This office, therefore, fell almost entirely upon him, and was his constant employment during the winter feafon.

In the fummer months of 1750, Mr Hunter attend. Hunter, ed the hospital at Chelsea; in 1751, he became a pupil at St Bartholomew's, and in the winter was present, at operations occasionally, whenever any thing extraordinary occurred. The following fummer he went to Scotland; and in 1753 entered, it is difficult to conceive for what reason, as a gentleman commoner at St Mary hall, Oxford. In 1754 he became a furgeon's pupil at St George's hospital, where he continued during the summer months; and in 1756 was appointed house-furgeon.

In the winter 1755, Dr Hunter admitted him to a partnership in his lectures, and a certain portion of the course was allotted to him; besides which, he gave lectures when the Doctor was called away to attend his patients. Making anatomical preparations was at this time a new art, and very little known; every preparation, therefore, that was skilfully made, became an object of admiration; many were wanting for the use of the lectures; and the Doctor being himself an enthufiast for the art, left no means untried to infuse into his brother a love for his favourite pursuits. How well he fucceeded, the collection afterwards made by Mr Hunter will fufficiently evince.

Anatomy feems to have been a pursuit for which Mr Hunter's mind was peculiarly fitted, and he applied to it with an ardour and perfeverance of which there is hardly any example. His labours were fo useful to his brother's collection, and fo gratifying to his disposition, that although in many other respects they did not agree, this simple tie kept them together for many years.

Mr Hunter worked for ten years on human anatomy, during which period he made himself master of what was already known, as well as made fome addition to that knowledge. He traced the ramifications of the olfactory nerves upon the membranes of the nofe, and discovered the course of some of the branches of the fifth pair of nerves. In the gravid uterus, he traced the arteries of the uterus to their termination in the placenta. He was also the first who discovered the existence of the lymphatic vessels in birds.

Many parts of the human body being fo complex, that their structure could not be understood, nor their uses ascertained, Mr Hunter was led to examine similar parts in other animals, in which the structure was more fimple, and more within the reach of investigation; this carried him into a wide field, and laid the foundation of his collection in comparative anatomy.

In this new line of pursuit, this active inquirer began with the more common animals, and preferved fuch parts as appeared by their analogy, or in some other way, to elucidate the human economy. It was not his intention

age, used for a year this receipt, given to me by an ancient hermit, whom I never faw before nor fince; and was not only cured, but recovered my strength, and appeared to all so remarkably beautiful, that the king of Poland asked me in marriage, he being a widower and I a widow. I, however, resused him for the love of my Lord Jesus Christ, from one of whose angels, I believe, I received the remedy. The receipt is as follows:

"R. Take of aqua vitæ, four times distilled, three parts, and of the tops and slowers of rosemary two parts: put these together in a close vessel, let them stand in a gentle heat 50 hours, and then distil them. Take one dram of this in the morning once every week, either in your food or drink, and let your face and the difeafed limb be washed with it every morning.

" It renovates the strength, brightens the spirits, purifies the marrow and nerves, restores and preserves the fight, and prolongs life." Thus far from the Breviary. Then follows a confirmation which Prevot gives from his own experience.

to inflitute an inquiry into the various organizations by which the functions of life are performed, that he might thereby acquire fome knowledge of general principles.

So eagerly did Mr Hunter attach himself to comparative anatomy, that he fought by every means in his power the opportunities of profecuting it with advantage. He applied to the keeper of wild bealts in the Tower for the bodies of those which died there; and he made fimilar applications to the men who showed wild beafts. He purchased all rare animals which came in his way; and thefe, with fuch others as were prefented to him by his friends, he entrusted to the showmen to keep till they died, the better to encourage them to affift him in his labours.

His health was fo much impaired by excessive attention to his pursuits, that in the year 1760 he was advifed to go abroad, having complaints in his breaft, which threatened to be consumptive. In October of that year, Mr Adair, inspector-general of hospitals, appointed him a furgeon on the staff; and in the following foring he went with the army to Bellisle, leaving Mr Hewson to affist his brother during his absence.

Mr Hunter served, while the war continued, as senior furgeon on the staff, both in Bellisse and Portugal, till the year 1763; and in that period acquired his knowledge of gun-shot wounds. On his return to England he settled in London; where, not finding the emoluments from his half-pay and private practice fufficient to support him, he taught practical anatomy and operative furgery for feveral winters. He returned also, with unabated ardour, to comparative anatomy; and as his experiments could not be carried on in a large town, he purchased for that purpose, about two miles from London, a piece of ground near Brompton, at a place called Earl's Court, on which he built a house. In the course of his inquiries, this excellent anatomist afcertained the changes which animal and vegetable fubstances undergo in the stomach when acted on by the gastric juice; he discovered, by means of feeding young animals with madder (which tinges growing bones red), the mode in which a bone retains its shape during its growth; and explained the process of exfoliation, by which a dead piece of bone is separated from the living.

His fondness for animals made him keep several of different kinds in his house, which by attention he rendered familiar with him, and amused himself by observing their peculiar habits and inflinets; but this familiarity was attended with confiderable risk, and sometimes led him into fituations of danger, of which the

following is a remarkable instance:

Two leopards, which were kept chained in an outhouse, had broken from their confinement, and got into the yard among fome dogs, which they immediately attacked; the howling this produced alarmed the whole neighbourhood; Mr Hunter ran into the yard to fee what was the matter, and found one of them getting up the wall to make his escape, the other furrounded by the dogs; he immediately laid hold of them both, and carried them back to their den; but as foon as they were fecured, and he had time to reflect upon the risk of his own fituation, he was fo much agitated, that he was in danger of fainting.

On the fifth of February 1767, he was chosen a fel-

nter. intention to make diffections of particular animals, but low of the Royal Society. His defire for improvement Hunter. in those branches of knowledge which might affift in his refearches, led him at this time to propose to Dr George Fordyce and Mr Cumming, an eminent mechanic, that they should adjourn from the meetings of the Royal Society to some coffee-house, and discuss such subjects as were connected with science. This planwas no fooner established, than they found their numbers increased; they were joined by Sir Joseph Banks, Dr Solander, Dr Maskelyne, Sir George Shuckburgh, Sir Harry Englefield, Sir Charles Blagden, Dr Noothe, Mr Ramsden, Mr Watt of Birmingham, and many others. At these meetings discoveries and improvements in different branches of philosophy were the objects of their confideration; and the works of the members were read over and criticifed before they were given to the public. It was in this year that, by an exertion in dancing, after the muscles of the leg were fatigued, he broke his tendo achillis. This accident, and the confinement in consequence of it, led him to pay attention to the subject of broken tendons, and to make a feries of experiments to ascertain the mode of their union.

In the year 176°, Mr Hunter became a member of the corporation of furgeons; and in the year following, through his brother's interest, he was elected one of the furgeons of St George's hospital. In May 1771, his Treatife on the Natural History of the Teeth was published; and in July of the same year he married Miss Home, the eldest daughter of Mr Home, surgeon to Burgoyne's regiment of light horse. 'The expence of his pursuits had been so great, that it was not till several years after his first engagement with this lady that his affairs could be fufficiently arranged to admit of his marrying.

Though after his marriage his private practice and professional character advanced rapidly, and though his family began to increase, he still devoted much of his. time to the forming of his collection, which, as it daily became larger, was also attended with greater expence. The whole suit of the best rooms in his house were occupied by his preparations; and he dedicated his mornings, from funrise to eight o'clock (the hour for breakfait), entirely to his pursuits. To these he added such parts of the day as were not engaged in attending his.

The knowledge he derived from his favourite studies he constantly applied to the improvement of the art of. furgery, and omitted no opportunity of examining morbid bodies; from which he made a collection of facts which are invaluable, as they tend to explain the real causes of symptoms, which during life could not be exactly afcertained, the judgment of the practitioner being too frequently milled by theoretical opinions, and

dehifive fensations of the patients.

In the practice of furgery, where cases occurred in which the operations proved inadequate to their intention, he always investigated, with uncommon care, the causes of that want of success; and in this way detected many fallacies, as well as made some important discoveries, in the healing art. He detected the cause of failure, common to all the operations in use for the radical sure of the hydrocele, and was enabled to propose a mode of operating, in which that event can with certainty be avoided. He afcertained, by experiments

Hunter, and observations, that exposure to atmospherical air fimply, can neither produce nor increase inflammation. He discovered in the blood so many phenomena connected with life, and not to be referred to any other cause, that he considered it as alive in its sluid state. He improved the operation for the fiftula lachrymalis, by removing a circular portion of the os unguis instead of breaking it down with the point of a trochar. He also discovered that the gastric juice had a power when the stomach was dead of dissolving it; and gave to the Royal Society a paper on this subject, which is published in the Philosophical Transactions.

> In the winter 1773, he formed a plan of giving a course of lectures on the theory and principles of furgery, with a view of laying before the public his own opinions upon that subject. For two winters he read his lectures gratis to the pupils of St George's Hospital; and in 1775, gave a course for money upon the same terms as the other teachers in the different branches of medicine and furgery. But giving lectures was always particularly unpleasant to him; fo that the defire of fubmitting his opinions to the world, and learning their general estimation, were scarcely sufficient to overcome his natural diflike to speaking in public. He never gave the first lecture of his course without taking 30 drops of laudanum to take off the effects of his uneafiness.

> Comparative anatomy may be confidered as the purfuit in which Mr Hunter was constantly employed. No opportunity escaped him. In the year 1773, at the request of his friend Mr Walsh, he diffected the torpedo, and laid before the Royal Society an account of its electrical organs. A young elephant, which had been presented to the Queen by Sir Robert Barker, died, and the body was given to Dr Hunter, which afforded Mr Hunter an opportunity of examining the flructure of that animal by affifting his brother in the diffection; fince that time two other elephants died in the Queen's menagerie, both of which came under Mr

Philosophical Transactions an account of certain receptacles of air in birds, which communicate with the lungs, and are lodged both among the fleshy parts and hollow bones of these animals; and a paper on the Gillaroo trout, commonly called in Ireland the Gizzard-

Hunter's examination. In 1774, he published in the

In 1775, feveral animals of that species, called the gymnotus electricus of Surinam, were brought alive to this country, and by their electrical properties excited very much the public attention. Mr Walsh, desirous of pursuing his investigations of animal electricity, made a number of experiments on the living animals; and to give his friend Mr Hunter an opportunity of examining them, purchased those that died. An anatomical account of their electrical organs was drawn up by Mr Hunter, and published in the Philosophical Transactions. In the same volume there is a paper of his, containing experiments on animals and vegetables respecting their power of producing heat.

In the course of his pursuits, Mr Hunter met with many parts of animals where natural appearances could not be preferved, and others, in which the minuter veffels could not be diffinctly feen when kept in spirits; at was therefore necessary to have them drawn, either at the moment, or before they were put into bottles.

The expence of employing professed draughtsmen, the Hunter, difficulty of procuring them, and the disadvantage which they laboured under in being ignorant of the subject they were to reprefent, made him defirous of having an able person in his house entirely for that purpose.

With this view he engaged an ingenious young artist to live with him for ten years; his time to be wholly employed as a draughtsman, and in making anatomical preparations. This gentleman, whose name was Bell, foon became a very good practical anatomist, and from that knowledge was enabled to give a spirited and accurate refemblance of the subjects he drew, such as is rarely to be met with in representations of anatomical subjects. By his labours Mr Hunter's collection is enriched with a confiderable number of very valuable drawings, and a great variety of curious and delicate anatomical preparations.

In January 1776, Mr Hunter was appointed furgeon extraordinary to his Majesty; and in the spring he gave to the Royal Society a paper on the best mode

of recovering drowned persons.

In the autumn he was taken extremely ill, and the nature of his complaints made his friends, as well as himself, consider his life to be in danger. When he reflected upon his own fituation, that all his fortune had been expended in his purfuits, and that his family had no provision but what should arise from the sale of his collection, he became very folicitous to give it its full value, by leaving it in a flate of arrangement. This he accomplished with the affistance of Mr Bell and his brother in law Mr Home.

In 1778, he published the second part of his Treatise on the Teeth, in which their diseases, and the mode of treatment are confidered. This rendered his work upon that subject complete. He published also in the Philosophical Transactions a paper on the Heat of Animals and Vegetables. In 1779, he published his account of the Free Martin in the Philosophical Transactions; and in 1780, he laid before the Royal Society an account of a woman who had the finall pox during pregnancy, where the difease seemed to have been communicated to the fœtus.

In 1781, he was elected a fellow of the Royal Society of Sciences and Belles Lettres at Gottenburg. And in 1782, he gave the Royal Society a paper on the Organ of Hearing in Fish. Besides the papers which he prefented to that learned body, he read fix Croonion lectures upon the subject of Muscular Action, for the years 1776, 1778, 1779, 1780, 1781, and 1782. In these lectures he collected all his observations upon muscles, respecting their powers and effects, and the stimuli by which they are affected; and to these he added Comparative Observations upon the moving Powers of Plants.

These lectures were not published in the Philosophical Transactions, for they were withdrawn as foon as read, not being confidered by the author as complete differtations, but rather as materials for some suture publication.

It is much to be regretted (fays Mr Home) that Mr Hunter was fo tardy in giving his observations to the public; but fuch was his turn for investigation, and fo extensive the scale upon which he instituted his inquiries, that he always found fomething more to be accomplished, and was unwilling to publish any thing which

anter. appeared to himself unfinished. His observations on the Muscular Action of the Blood-vessels were laid before the Royal Society in 1780, and yet he delayed publishing them till his Observations on the Blood and Inflammation were arranged; and they make part of the volume which was published after his death.

In 1783, he was chosen into the Royal Society of Medicine and the Royal Academy of Surgery in Paris; and the same year the lease of the house which he occupied in Jermyn freet having expired, he purchased the lease of a large house on the east-side of Leicesterfquare, and the whole lot of ground adjoining to Caftlefireet, on which there was another house. In the middle space between the two houses, he erected, at the expence of L.3000, a building for his collection; though, unfortunately for his family, the leafe did not extend beyond 24 years.

In the building formed for the collection there was a room fifty two feet long, by twenty eight feet wide, lighted from the top, and having a gallery all round, for containing his preparations. Under this were two apartments; one for his lectures, and the other, with no particular destination at first, but afterwards made use of for weekly meetings of medical friends during the winter. To this building the house in Castle-street was entirely subservient; and the rooms in it were used for the different branches of human and comparative ana-

About this period Mr Hunter may be considered as at the height of his chirurgical career; his mind and body were both in their full vigour. His hands were capable of performing whatever was fuggefted by his mind; and his judgment was matured by former experience. Some instances of his extraordinary skill may very properly be mentioned.

He removed a tumor from the fide of the head and neck of a patient at St George's Hospital, as large as the head to which it was attached; and by bringing the cut edges of the ikin together, the whole was nearly healed by the first intention.

He diffected out a tumor on the neck, which one of the best operating furgeons in this country had declared, rather too itrongly, that no one but a fool or a madınan would attempt; and the patient got perfectly well.

He discovered a new mode of performing the operation for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh, without doing any thing to the tumor in the ham. The fafety and efficacy of this mode have been confirmed by many subsequent trials; and it must be allowed to stand very high among the modern improvements in furgery.

If we consider Mr Hunter at this period of his life, it will afford us a strong picture of the turn of his mind, of his defire to acquire knowledge, and his unremitting affidnity in profecuting whatever was the object of his

attention. He was engaged in a very extensive private practice; he was furgeon to St George's Hospital; he was giving a very long course of lectures in the winter; he was carrying on his inquiries in comparative anatomy; had a school of practical human anatomy in his house; and was always employed in some experiments respecting the animal economy.

He was always folicitous for fome improvement in

medical education; and, with the affiftance of Dr For- Hunter. dyce, instituted a medical society, which he allowed to meet in his lecture-rooms, and of which he was chofen one of the patrons. This fociety, called the Lyceum Medicum Londinense, under his au pices and those of Dr Fordyce, has acquired confiderable reputation, both from the numbers and merits of its members.

In the year 1786, in confequence of the death of Mr Middleton, Mr Hunter was appointed deputy surgeongeneral to the army. He now published his work upon the Venereal Disease, which had been long expected by the public; and, if we may judge from the rapid fale of the first edition, these expectations have not been disappointed. He also published a work entitled, Obfervations on certain Parts of the Animal Economy, In this work he has collected feveral of his papers inferted in the Philosophical Transactions, which related to that subject, having permission from the president and council of the Royal Society to reprint them; there are also Observations upon some other Parts of the Animal Economy, which had not before been published. This work met with a very ready fale.

In the year 1787, he gave a paper to the Royal Society, containing an Experiment to determine the Effect of extirpating one Ovarium on the Number of Young; a paper in which the wolf, jackall, and dog, are proved to be of the same species; and a third upon the Anatomy of the Whale Tribe. These papers procured him the honour of receiving Sir John Copley's annual gold medal, given as a mark of distinguished abilities.

His collection, which had been the great object of his life, both as a pursuit and an amusement, was now brought into a flate of arrangement; and gave him at length the satisfaction of shewing to the public a series of anatomical facts formed into a fystem, by which the economy of animal life was illustrated. He shewed it to his friends and acquaintances twice a-year, in October to medical gentlemen, and in May to noblemen and gentlemen, who were only in town during the fpring. This custom he continued to his death.

Upon the death of Mr Adair, which happened in the year 1792, Mr Hunter was appointed inspector-general of hospitals, and surgeon general to the army. He was also elected a member of the Royal College of Surgeons in Ireland. In the year 1791, he was so much engaged in the duties of his office, as furgeon-general to the army, and his private practice, that he had little time to bestow upon his scientifical objects; but his leisure time, small as it was, he wholly devoted to them.

In 1792, he was elected an honorary member of the Chirurgo-Phyfical Society of Edinburgh, and was chofen one of the vice-presidents of the Veterinary College, then first established in London. He published in the Transactions of the Society for the Improvement of medical and chirurgical Knowledge, of which fociety her was one of the original members and a zealous promoter, three papers on the following subjects: Upon the Treatment of Inflamed Veins, on In osusception, and on a Mode of conveying Food into the Stomach in Cases of Paralysis of the Esophagus.

He finished his Observations on the Economy of Bees, and presented them to the Royal Society. These obfervations were made at Earl's Court, and had engaged his attention for many years; every inquiry into the economy of these insects had been attended by almost

unfurmountable

Hunter. unfurmountable difficulties; but these proved to him Wounds, the reader will find one of the most complete Hunter, of to bring the different operations of these indefatigable animals to view were almost without end.

Earl's Court to Mr Hunter was a retirement from the fatigues of his profession; but in no respect a retreat from his labours; there, on the contrary, they were carried on with lefs interruption, and with an unwearied perseverance. From the year 1772 till his death, lie made it his custom to sleep there during the autumn months, coming to town only during the hours of bufinefs in the forenoon, and returning to dinner.

It was there he carried on his experiments on digestion, on exfoliation, on the transplanting of teeth into the combs of cocks, and all his other investigations on the animal economy, as well in health as in difeafe. The common bee was not alone the subject of his obfervation, but the wasp, hornet, and the less known kinds of bees, were also objects of his attention. It was there he made the series of preparations of the external and internal changes of the filk worm; also a series of the incubation of the egg, with a very valuable fet of drawings of the whole feries. The growth of vegetables was also a favourite subject of inquiry, and one on which he was always engaged in making experiments.

The collection of comparative anatomy which Mr Hunter has left, and which may be confidered as the great object of his life, must be allowed to be a proof of talents, affiduity, and labour, which cannot be contemplated without furprise and admiration. It remains an unequivocal test of his perseverance and abilities, and an honour to the country in whose schools he was educated, and by the patronage of which he was enabled on so extensive a scale to carry on his pursuits. In this collection we find an attempt to expose to view the gradations of Nature, from the most simple state in which life is found to exist, up to the most perfect and most complex of the animal creation-man himfelf.

By the powers of his art, this collector has been enabled so to expose, and preserve in spirits or in a dried state, the different parts of animal bodies intended for fimilar uses, that the various links of the chain of perfection are readily followed and may be clearly understood.

This collection of anatomical facts is arranged according to the subjects they are intended to illustrate, which are placed in the following order: First, Parts constructed for motion. Secondly, Parts essential to animals refpecting their own internal economy. Thirdly, Parts superadded for purposes connected with external objects. Fourthly, Parts for the propagation of the species and maintenance or fupport of the young.

Mr Hunter was a very healthy man for the first forty years of his life; and, if we except an inflammation of his lungs in the year 1759, occasioned most probably by his attention to anatomical purfuits, he had no complaint of any consequence during that period. In the spring of 1769, in his forty-first year, he had a regular fit of the gout, which returned the three following fprings, but not the fourth; and in the spring of 1773, having met with fomething which very forcibly affected his mind, he was attacked at ten o'clock in the forenoon with a pain in the stomach, attended with all the fymptoms of angina pectoris. In the life of him prefixed to his Treatife on the Blood, Inflammation, and Gun-Shot

only an incitement, and the contrivances he made use histories of that disease upon record. Suffice it, in this place, to fay, that for twenty years he was subject to frequent and fevere attacks of it, which however did not, till a short time before his death, either impair his judgment or render him incapable of performing operations in furgery. "In autumn 1790 (fays Mr Home). and in the spring and autumn 1791, he had more severe attacks than during the other periods of the year, but of not more than a few hours duration: in the beginning of October 1792, one, at which I was present, was fo violent that I thought he would have died. On October the 16th, 1793, when in his usual state of health, he went to St George's Hospital, and meeting with fome things which irritated his mind, and not being perfectly master of the circumstances, he withheld his fentiments; in which state of restraint he went into the next room, and turning round to Dr Robertson, one of the physicians of the hospital, he gave a deep groan and dropt down dead; being then in his 65th year, the same age at which his brother Dr Hunter had died."

It is a curious circumstance, that the first attack of these complaints was produced by an affection of the mind, and every future return of any consequence arose from the same cause; and although bodily exercise, or distention of the stomach, brought on slighter affections, it still required the mind to be affected to render them fevere; and as his mind was irritated by trifles, thefe produced the most violent effects on the disease. His coachman being beyond his time, or a servant not attending to his directions, brought on the spasms, while a real misfortune produced no effect.

Mr Hunter was of a short stature, uncommonly strong and active, very compactly made, and capable of great bodily exertion. His countenance was animated, open, and in the latter part of his life deeply impressed with thoughtfulness. When his print was shewn to Lavater, he faid, "That man thinks for himself." In his youth he was cheerful in his disposition, and entered into vouthful follies like others of the fame age; but wine never agreed with his stomach; so that after some time he left it off altogether, and for the last twenty years drank nothing but water.

I-lis temper was very warm and impatient, readily provoked, and, when irritated, not easily soothed. His difposition was candid, and free from referve, even to a fault. He hated deceit; and as he was above every kind of artifice, he detefted it in others, and too openly avowed his fentiments. His mind was uncommonly active; it was naturally formed for investigation, and that turn displayed itself on the most trivial occasions, and always with mathematical exactness. What is curious, it fatigued him to be long in a mixed company which did not admit of connected conversation; more particularly during the last ten years of his life.

He required lefs relaxation than most other men; feldom fleeping more than four hours in the night, but almost always nearly an hour after dinner; this, probably, arose from the natural turn of his mind being fo much adapted to his own occupations, that they were in reality his amusement, and therefore did not fatigue.

In private practice he was liberal, ferupulously honest in faying what was really his opinion of the case, and ready upon all occasions to acknowledge his ignorance,

nters whenever there was any thing which he did not under-

In conversation, he spoke too freely, and sometimes harshly, of his contemporaries; but if he did not do justice to their undoubted merits, it arose not from envy, but from his thorough conviction that surgery was as yet in its infancy, and he himself a novice in his own art; and his anxiety to have it carried to perfection, made him think meanly and ill of every one whose exertions in that respect did not equal his own.

HURTERS, in fortification, denote pieces of timber, about fix inches fquare, placed at the lower end of the platform, next to the parapet, to prevent the wheels of the gun carriages from damaging the parapet.

HYDROGRAPHICAL CHARTS or MAPS, more usually called sea-charts, are projections of some part of the sea, or coast, for the use of navigation. In these are laid down all the rhumbs or points of the compass, the meridians, parallels, &c. with the coasts, capes, islands, rocks, shoals, shallows, &c. in their proper places, and proportions.

HYDROMETER, is an instrument, of which so much has been said in the Encycl. under that title, and in the article Specific Gravity, that we certainly should not again introduce it in this place, but to guard our readers against error, when studying the works of the French chemists. These gentlemen, who are so strongly attached to every thing which is new, as to believe that their ancestors have for ages been wandering in the mazes of ignorance, refer very frequently to the pese-liqueur of Baumé; and as that instrument has never been generally used in this country, it becomes our duty to describe its construction.

Instead of adopting the simpler method of immediate numerical reference to the density of water expressed by unity, as is done in all modern tables of specific gravity, he had recourse to a process similar to that of graduating the stems of thermometers from two fixed points. The first of these points was obtained by immerfing his instrument, which is the common areometer, confisting of a ball, stem, and counterpoise, in pure water. At that point of the stem which was intersected by the furface of the fluid, he marked zero, or the commencement of his graduations. In the next place, he provided a number of folutions of pure dry common falt in water: these folutions contained respectively one, two, three, four, &c. pounds of the falt; and in each folution the quantity of water was fuch, as to make up the weight equal to one hundred pounds in the whole; fo that in the folution containing one pound of falt, there were ninety-nine pounds of water; in the folution containing two pounds of falt, there were ninety-eight pounds of water, and so of the rest. The instrument was then plunged in the first folution, in which of course it floated with a larger portion of the stem above the sluid, than when pure water was used. The fluid, by the intersection of its surface upon the stem, indicated the place for marking his first degree; the same operation repeated, with the fluid containing two pounds of falt, indicated the mark for the fecond degree; the folution of three pounds afforded the third degree; and in this manner his enumera-tion was carried as far as fifteen degrees. The first fifteen degrees afterwards, applied with the compasses

SUPPL. VOL. I. Part II.

repeatedly along the stem, served to extend the gradua. Hydrus, tion as far as eighty degrees, if required.

This instrument, which is applicable to the admeafurement of densities exceeding that of pure water, is commonly distinguished by the name of the *Hydrome*ter for salts.

The hydrometer for spirits is constructed upon the same principle; but in this the counterpoise is so adjusted, that most part of the stem rises above the sluid when immersed in pure water, and the graduations to express inferior densities are continued upwards. A solution of ten parts by weight of salt in ninety parts of pure water, affords the first point, or zero, upon the stem; and the mark indicated by pure water is called the tenth degree; whence, by equal divisions, the remaining degrees are continued upwards upon the stem as far as the siftieth degree.

These experiments, in both cases, are made at the tenth degree of Reaumur, which answers very nearly to fifty-five of Fahrenheit.

HYDRUS, or WATER SERPENT, one of the new fouthern conftellations, including only ten stars.

HYGROMETER, is an inftrument of fo much importance to the meteorologist, that it becomes us to give some account of every improvement of it which has fallen under our notice. In the *Encyclopædia*, the principles upon which hygrometers are constructed have been clearly stated, and the defects of each kind of hygrometer pointed out.

Instead of hairs or cat-gut, of which hygrometers of the first kind are commonly made, Cassebois, a Benedictine monk at Mentz, proposed to make such hygrometers of the gut of a filk worm. When that infect is ready to spin, there are found in it two vessels proceeding from the head to the stomach, to which they adhere, and then bend towards the back, where they form a great many folds. The part of these vesfels next the stomach is of a cylindric form, and about a line in diameter. These vessels contain a gummy fort of matter from which the worm spins its filk; and, though they are exceedingly tender, means have been devifed to extract them from the infect, and to prepare them for the above purpose. When the worm is about to spin, it is thrown into vinegar, and suffered to remain there twenty four hours; during which time the vinegar is absorbed into the body of the infect, and coagulates its juices. The worm being then opened, both the veffels, which have now acquired strength, are extracted; and, on account of their pliability, are capable of confiderable extension. That they may not, however, become too weak, they are stretched only to the length of about fifteen or twenty inches. It is obvious that they must be kept sufficiently extended till they are completely dry. Before they attain to that state, they must be freed, by means of the nail of the finger, from a slimy substance which adheres to them. Such a thread will fustain a weight of fix pounds without breaking, and may be used for an hygrometer in the same manner as cat-gut; but we confess that we do not clearly perceive its superiority.

To an improvement of the hygrometer conftructed on the third principle, stated in the Encyclopedia, M. Hochheimer was led in the following manner:

Mr Lowitz found at Dmitriewik in Astracan, on the

Hygrome- the banks of the Wolga, a thin bluish kind of slate which attracted moisture remarkably soon, but again fuffered it as foon to escape. A plate of this slate weighed, when brought to a red heat, 175 grains, and, when faturated with water, 247: it had therefore imbibed, between complete dryness and the point of complete moisture, 72 grains of water. Lowitz suspended a round thin plate of this flate at the end of a very delicate balance, fastened within a wooden frame, and fuspended at the other arm a chain of filver wire, the end of which was made fast to a sliding nut that moved up and down in a small groove on the edge of one side of the frame. He determined, by trial, the position of the nut when the balance was in equilibrio and when it had ten degrees of over-weight, and divided the space between these two points into ten equal parts, adding fuch a number more of these parts as might be necesfary. When the stone was suspended from the one arm of the balance, and at the other a weight equal to 175 grains, or the weight of the stone when perfectly dry, the nut in the groove shewed the excess of weight in grains when it and the chain were fo adjusted that the balance stood in equilibrio. A particular apparatus on the same principles as a vernier, applied to the nut, shewed the excess of weight to ten parts of a grain. Lowitz remarked that this hygrometer in continued wet weather gave a moisture of more than 55 grains, and in a continued hear of 113 degrees of Fahrenheit only 11 degree of moisture.

The hygrometer thus invented by Lowitz was, however, attended with this fault, that it never threw off the moisture in the same degree as the atmosphere became drier. It was also sometimes very deceitful, and announced moisture when it ought to have indicated that dryness had again begun to take place in the atmosphere. To avoid these inconveniencies, M. Hoch-

heimer proposes the following method:

1. Take a square bar of steel about two lines in thickness, and from ten to twelve inches in length, and form it into a kind of balance, one arm of which ends in a screw. On this screw let there be screwed a leaden bullet of a proper weight, instead of the common

weights that are suspended. 2. Take a glass plate Hygrome. about ten inches long, and feven inches in breadth, deftroy its polish on both fides, free it from all moisture Hypotra. by rubbing it over with warm ashes, suspend it at the chelion, other end of the balance, and bring the balance into equilibrium by screwing up or down the leaden bullet. 3. Mark now the place to which the leaden bullet is brought by the fcrew, as accurately as possible, for the point of the greatest dryness. 4. Then take away the glass plate from the balance, dip it completely in water, give it a shake that the drops may run off from it, and wipe them carefully from the edge. 5. Apply the glafs-plate thus moistened again to the balance, and bring the latter into equilibrium by screwing the leaden bullet. Mark then the place at which the bullet stands as the highest degree of moisture. 6. This apparatus is to be suspended in a small box of well dried wood, fufficiently large to fuffer the glass-plate to move up and down. An opening must be made in the lid, exactly of fuch a fize as to allow the tongue of the balance to move freely. Parallel to the tongue apply a graduated circle, divided into a number of degrees at pleasure from the highest point of dryness to the highest degree of moisture. The box must be pierced with fmall holes on all the four tides, to give a free passage to the air; and to prevent moisture from penetrating into the wood by rain, when it may be requifite to expose it at a window, it must either be lackered or painted. To fave it at all times from rain, it may be covered, however, with a fort of roof fitted to it in the most convenient manner. But all these external appendages may be improved or altered as may be found neceffary.

HYPEBOLA DEFICIENT, is a curve having only one afymptote, though two hyperbolic legs running out infinitely by the fide of the asymptote, but contrary ways.

HYPOTRACHELION, in Architecture, is used for a little frize in the Tufcan and Doric capital, between the astragal and annulets; called also the colerin and gorgerin. The word is applied by some authors in a more general fense, to the neck of any column, or that part of its capital below the aftragal.

Jacobins. TACOBINS, in the language of the present day, is the name affumed, at the beginning of the French revolution, by a party in Paris, which was outragioufly democratical, and fanatically impious. This party, which confifted of members of the National Affembly, and of others maintaining the fame opinions and purfuing the fame objects, formed itself into a club, and held its meetings in the hall belonging to the jacobin friars, where measures were fecretly concerted for exciting infurrections, and over-awing at once the legislature and the king. The name of Jacobin, though it was derived from the hall where the club first met, has fince been extended to all who are enemies to monarchy, ariftocracy, and the Christian religion; and who would have every man to be his own prieft and his own lawgiver. Hence it is, that we have Jaco-

bins in Great Britain and Ireland, as well as in France. Jacobin

Of the proceedings of the French Jacobins, some account has been given, in the Encyclopadia, under the title REVOLUTION, and the subject will be resumed in this Supplement under the same title. The purpose of the present article is to trace the principles of the sect. from their source; for these principles are not of yester-

"At its very first appearance, (says the Abbé Barruel), this feet counted 300,000 adepts; and it was supported by two millions of men, scattered through France, armed with torches and pikes, and all the fire. brands of the revolution." Such a wide spread conspiracy could not be formed in an instant; and indeed this able writer has completely proved, that this fect, with all its conspiracies, is in itself no other than "the coalition

obins of a triple fect, of a triple conspiracy, in which, long before the revolution, the overthrow of the altar, the ruin of the throne, and the diffolution of all civil fociety, had been debated and determined."

It is known to every scholar, that there have been in all ages and countries men of letters and pretenders to letters, who have endeavoured to fignalize themselves individually by writing against the religion of their country; but it was referved for the philosophists (A) of France to enter into a combination for the express purpose of eradicating from the human heart every religious sentiment. The man to whom this idea first occurred was Voltaire; who, daring to be jealous of his God, and being weary, as he faid himfelf, of hearing people repeat that twelve men were sufficient to establish Christianity, resolved to prove that one might be sufficient to overthrow it. Full of this project, he swore, before the year 1730, to dedicate his life to its accomplishment; and for some time he flattered himfelf that he should enjoy alone the glory of destroying the Christian religion. He found, however, that affociates would be necessary; and from the numerous tribe of his admirers and disciples, he chose D'Alembert and Diderot as the most proper persons to cooperate with him in his defigns. How admirably they were qualified to act the part affigned them, may be conceived from the life of DIDEROT in this Supplement. But Voltaire was not satisfied with their aid alone.

He contrived to embark in the same cause Frederic II. of Prussia, who wished to be thought a philosopher, and who of course deemed it expedient to talk and write against a religion which he had never studied, and into the evidence of which he had probably never deigned to enquire. This royal adept was one of the most zealous of Voltaire's coadjutors, till he difcovered that the philosophists were waging war with the throne as well as with the altar. This indeed was not originally Voltaire's intention. He was vain; he loved to be careffed by the great; and, in one word, he was, from natural disposition, an aristocrate and admirer of royalty: But when he found that almost every sovereign, but Frederic, disapproved of his impious projects as soon as he perceived their iffue, he determined to oppose all the governments on earth, rather than forfeit the glory, with which he had flattered himself, of vanquishing Christ and his apostles in the field of controverly.

He now fet himfelf, with D'Alembert and Diderot, to excite universal discontent with the established order of things. This was an employment entirely fuited to their disposition; for not being in any seuse great themfelves (B), they wished to pull all men down to their cieties, assumed new names, and employed an enigma- fate. Yet think not, indignant reader, that the ways

tical language. Thus, Frederic is called Luc; D'Alem- Jacobins. bert, Protagoras, and sometimes Bertrand; Voltaire, Raton; and Diderot, Platon, or its anagram Tonpla; while the general term for the conspirators is Cacoucc. In their fecret meetings they professed to celebrate the mysteries of Mythra; and their great object, as they professed to one another, was to confound the wretch, meaning J-C-. Voltaire proposed to establish a colony of philosophists at Cleves, who, protected by the king of Prussia, might publish their opinions without dread or danger; and Frederic was disposed to take them under his protection, till he discovered that their opinions were anarchical as well as impious, when he threw them off, and even wrote against them.

They contrived, however, to engage the ministers of the court of France in their favour, by pretending to have nothing in view but the enlargement of science, in works which spoke indeed respectfully of revelation, while every discovery which they brought forward was meant to undermine its very foundation. When the throne was to be attacked, and even when barefaced atheism was to be promulgated, a number of impious and licentious pamphlets were dispersed, for some time none knew how, from a fecret fociety formed at the Hotel d'Holbach at Paris. These were sold for trifles, or distributed gratis to schoolmasters, and others who were likely to circulate their contents. D'Alembert, Diderot, and Condorcet, who was now affociated with the other conspirators, flattered the ambition of every man among the great, and cspecially of the Duke d'Orleans, the richest subject in Europe, and a prince of the blood of France. The first and the last of these three adepts had, by their mathematical knowledge, got fuch an ascendancy in the Royal Academy of Sciences, that they could admit or exclude candidates as they knew them to be friendly or inimical to the projects of the conspirators; and they had contrived, by matchless address and unwearied perseverance, to fill almost all the feminaries of education with men of their own prin-

Thus was the public mind in France completely corrupted, when the mason lodges, over which the infamous Orleans prefided, were vifited by a delegation from the German illuminati; and nothing more was necessary to produce the fect of Jacobins, by whose intrigues and influence, France, as M. Barrucl expresses himself, has become a prey to every crime. It was by the machinations of this feet that its foil was flained with the blood of its pontiffs and priefts, its rich men and nobles; with the blood of every class of its citizens, without rcgard to rank, age, or fex. These disciples of Voltaire were the men who, after having made the unfortunate own level. How effectually they contrived to convert Louis, his queen, and fifter, drink, to the very dregs, the Encyclopadie into an engine to serve their purposes, the cup of outrage and ignominy during a long confinehas been shown already; but it was not their only nor ment, solemnly murdered them on a scaffold, proudly their most powerful engine; they formed fecret for menacing all the fovereigns of the earth with a fimilar

5 D 2

(A) This term was invented by Abbé Barruel, and we have adopted it, as denoting fomething very different from the meaning of the word philosopher.

⁽B) We do not by this mean to infinnate that D'Alembert was not a man of science. He was perhaps the only man of science in that gang; but he was a master of no science but mathematics; and his birth being obscure, if not spurious, and abstract mathematics not furnishing ready access to the great, his ideas, when compared with Voltaire's, were grovelling, and (as M. Barruel fays) he was afraid to be feen.

Jaghire Il Jago.

of Providence are unequal. The nations of Europe were ripe for chastisement; and that chastisement these villains were employed to inslict: but their own punishment did not linger. Voltaire died in agonies of desponding remorfe, which can be exceeded only by the torments of the damned. There is reason to believe that the end of D'Alembert and Diderot very much resembled that of their leader; while the more hardened adept, Condorcet, became his own executioner; and the other chiefs of the rebellion have regularly inslicted vengeance on each other, every alteration of the French constitution (and these alterations have been many) being followed by the execution of those by whom the government was previously administered.

JAGHIRE, affigument made in Bengal by an Imperial grant upon the revenue of any diffrict, to defray civil or military charges, penfions, gratuities, &c.

JAGHIREDER, the holder of a Jaghire. ST JAGO, the largest and most populous of the Cape de Verde Islands, of which some account has been given in the Encyclopædia, is represented by Sir George Staunton as liable to long and excessive droughts, for which no philosophical cause can be affigned. When the embassy to China touched at it in the latter end of 1702, it was in a state of absolute famine. Little or no rain had fallen for about three years before. The rivers were almost all entirely dry. The furface of the earth was, in general, naked of any herbage. The greatest part of the cattle had perished, not less through drought than want of food. Of the inhabitants many had migrated, and many were famished to death. Nor was this calamity peculiar to St Jago. All the islands of Cape de Verde were faid to have experienced the same long drought, and to be consequently in a state of similar desolation. Yet the frequent showers which were observed by the first navigators who touched at St Jago, induced them to give to the island the name of Pluivalis; and no change had been observed in the fleady current of wind, blowing from the east, which is common to tropical climates.

"What were the uncommon circumstances (fays Sir George) that took place in the atmosphere of that part of Africa to which the Cape de Verde islands lie contiguous, or in the vast expanse of continent extending to the east behind it, and from which this direful effect must have proceeded (as they happened where no man of science existed to observe or to record them), will therefore remain unknown; nor is theory bold enough to supply the place of observation. Whatever was the cause which thus arrested the bountiful hand of Nature, by drawing away the fources of fertility, it was observable, that some few trees and plants persevered to flourish with a luxuriance, indicating that they still could extract from the arid earth whatever portion of humidity it was necessary to derive from thence for the purpose of vegetable life, though it was denied to others."

Beside the trees of the palm kind, which are often found verdant amidst burning sands, nothing, for example, could be more rich in slavour, or abound more with milky, though corrosive juice, than the asclepias gigantea (see Asclepias, Encycl.), growing plentifully, about several feet high, without culture, indeed, but undisturbed, it being of no avail to cut it down in savour of plants that would be useful, but required the aid of more moisture from the atmosphere. The jatro-

pha curcas, or physic nut tree, which the French West Indians, with fome propriety, call bois immortel, and plant, on that account, in the boundaries of their estates, appeared as if its perpetuity was not to be affected by any drought. Some indigo plants were still cultivated with fuccess in shaded vales, together with a few cotton shrubs. Throughout the country some of those fpecies of the mimofa, or fenfitive plant, which grow into the fize of trees, were most common, and did not appear to languish. In particular spots the annona, or fugar apple tree, was in perfect verdure. The boraffus, or great fair palm, lifted, in a few places, its lofty head and spreading leaves with undiminished beauty. In a bottom, about a mile and a half behind the town of Praya, was still growing, in a healthy state, what may be called for fize a phenomenon in vegetation, a tree known to botanists by the name of adamsonia, and in English called monkey bread tree. The natives of St Jago call it kabifera; others, baobab. Its trunk mea-fured at the base no less than 56 feet in girth; but it foon divided into two great branches, one rifing perpendicularly, and measuring 42 feet in circumference. That of the other was about 26. By it stood another of the fame species, whose fingle trunk, of 38 feet girth, attracted little notice from the vicinity of its huge com-

But the annual produce of agriculture was scarcely to be sound. The plains and fields, formerly productive of corn, sugar-canes, or plantains, nourished by regular falls of rain, now bore little semblance of vegetation. Yet in the small number of plants which survived the drought, were some which, from the specimens sent to Europe, were sound to have been hitherto unknown. Vegetation quickly, indeed, revived wherever, through the soil, any moisture could be conveyed.

Sir George reprefents Praya, the residence of the Portuguese Viceroy, as a hamlet rather than a town. It consists of about 100 very small dwellings, one story high, scattered on each side of the plain, which extended near a mile in length, and about the third of a mile in breadth; and sell off, all around, to the neighbouring valleys and to the sea. Not being commanded by any neighbouring eminence, it was a situation capable of desence; the fort, however, or battery, was almost in ruins; and the sew guns mounted on it were mostly honey-combed, and placed on carriages which scarcely held together.

A party belonging to the embaffy croffed the country to the ruins of St Jago, the former capital of the island, situated in the bottom of a vale, through which ran a stream, then both small and sluggish. On each fide of that stream are the remains of dwellings of confiderable folidity and fize; and the fragments of glass lustres, still hanging from the ceilings of some of the principal apartments, denote the elegance or riches that were once displayed in this now deserted place. Not above half a dozen families remain in it at present; the rest abandoned it, or perished. Here was still, however, an attempt at a flight manufactory of striped cotton slips, the same as are made in the other parts of the island, for the use of the Africans on the main, who pay for them in slaves, elephants teeth, and that gum which is generally called arabic.

Amidst the ruins of St Jago, the party found a Portuguese, to whom one of them was recommended, and

who

his house, and treated them with every species of tropical fruits from his garden, lying on each fide the river.

He had been a navigator; and informed them that the isle of Brava, one of the Cape de Verde's, was a fitter and fafer place for ships to call at for water and provisions than the island of St Jago; that it had three harbours; one called Puerto Furno on the east side of the island, from which vessels must warp, or be towed out by boats; the Puerto Fajendago to the west; and the Puerto Ferreo to the fouth, which was the best for large ships, and into which runs a small river. In another of the Cape de Veide islands, called San Vicenté, he observed that there was also a large harbour on the north end, but that fresh water was at some distance from it: and there was likewife a good port at Bonavista. This information of the harbours in the ifle of Brava was confirmed by accounts given by others to Sir Erasmus Gower, who recommends to make a trial

JALOFFS, or YALOFFS, are an active, powerful, and warlike people, inhabiting great part of that tract of Africa which lies between the Senegal and the Mandingo states on the Gambia (See MANDINGOES in this Supplement). Their nofes, fays Mr Park, are not fo much depressed, nor their lips so protuberant, as those of the generality of Africans; and though their skin is of the deepest black, they are considered by the white traders as the most fightly Negroes in that part of the continent where they live. They are divided into feveral independent states or kingdoms, which are frequently at war with their neighbours or with each other. In their manners, fuperstitions, and government, they have a greater resemblance to the Mandingoes than to any other nation; but excel them in the manufacture of cotton cloth, spinning the wool to a finer thread, weaving it in a broader loom, and dyeing it of a better colour. They make very good foap, by boiling ground nuts in water, and then adding a ley of wood ashes. They likewise manufacture excellent iron, which they carry to Bondou to barter for falt. Their language is faid to be copious and fignificant, and is often learned by Europeans trading to Senegal. From the names of their numerals, as given by Mr Park, it would appear that their numeration proceeds by fives, as ours does by tens.

Our author relates the event of a religious war, which, as it displays a generosity of character very uncommon among favages, will afford pleasure to the minds of many of our readers. Almami Abdulkader, sovereign of a Mahomedan kingdom called Foota Torra, fent to Damel, a king of the Jaloffs, an imperious mef-fage, commanding him and his subjects to embrace instantly the faith of the prophet. The ambassador having got admission to the presence of Damel, ordered some Bushreens (i. e. Mahomedan Negroes) who accompanied him, to present the emblems of his mission. Two knives were accordingly laid before the Jaloff prince, and the ambaffador explained himself as follows:

"With this knife (faid he) Abdulkader will condefcend to shave the head of Damel, if Damel will embrace the Mahomedan faith; and with this other knife Abdulkader will cut the throat of Damel, if Damel refuses to embrace it: Take your choice."-Damel coolly told the ambaffador that he had no choice to make:

offs. who received them with the most cordial hospitality in he neither chose to have his head shaved, nor his throat Jaloss, cut. And with this answer the ambassador was civilly Jarra. difmissed.

Abdulkader took his measures accordingly; and with a powerful army invaded Damel's country. The inhabitants of the towns and villages filled up their wells, destroyed their provisions, carried off their effects, and abandoned their dwellings, as he approached. By this means he was led on from place to place, until he had advanced three days journey into the country of the Jaloffs. He had, indeed, met with no opposition; but his army had fuffered fo much from the fcarcity of water, that several of his men died by the way. This induced him to direct his march towards a watering place in the woods, where his men, having quenched their thirst, and being overcome with fatigue, lay down carclefsly to fleep among the bushes. In this fituation they were attacked by Damel before day break, and completely routed. Many of them were trampled to death as they lay afleep by the Jaloffs horfes; others were killed in attempting to make their escape; and a still greater number were taken prisoners. Among the latter was Abdulkader himself. This ambitious, or rather frantic prince, who, but a month before, had fent the threatening message to Damel, was now himself led into his presence as a miserable captive. The behaviour of Damel, on this occasion, is never mentioned by the finging men * but in terms of the highest ap. * The bifton probation; and it was, indeed, fo extraordinary in an rians of the African prince, that the reader may find it difficult to country. give credit to the recital. When his royal prisoner was. brought before him in irons, and thrown upon the ground, the magnanimous Damel, instead of fetting his foot upon his neck, and stabbing him with his spear, according to the custom in such cases, addressed him as follows: "Abdulkader, answer me this question. If the chance of war had placed me in your fituation, and you in mine, how would you have treated me?" " I would have thrust my spear into your heart (returned Abdulkader with great firmness); and I know that a similar fate awaits me." "Not so (faid Damel); my spear is indeed red with the blood of your subjects killed in battle, and I could now give it a deeper stain, by dipping it in your own; but this would not build up my towns, nor bring to life the thousands who fell in the woods. I will not therefore kill you in cold blood, but I will retain you as my flave, until I perceive that your presence in your own kingdom will be no longer dangerous to your neighbours; and then I will confider of the proper way of disposing of you." Abdulkader was accordingly retained, and worked as a flave for three months; at the end of which period, Damel liftened to the folicitations of the inhabitants of Foota Torra, and restored to them their king. Strange as this story may appear, Mr Park has no doubt of the truth of it. It was told to him at Malacotta by the Negroes; it was afterwards related to him by the Europeans on the Gambia; by some of the French at Goree; and confirmed by nine slaves, who were taken prisoners along with Abdulkader by the watering place in the woods, and carried in the same ship with him to the West Indies .- Such generofity as this reslects honour on human nature.

JARRA, is a town of confiderable extent in the Moorish kingdom of Ludamar in Africa. The houses

are built of clay and stone intermixed, a kind of wall fome grass or green fods, covered with dung from the Ichnogra lee house, very common in many parts of Scotland, where clay is made to supply the place of mortar. The greater part of the inhabitants of Jarra are Negrocs from the borders of the fouthern states, who prefer, fays Mr Park, a precarious protection under the Moors, which they purchase by a tribute, to the being continually exposed to their predatory hostilities. The tribute which they pay is confiderable; and they manifest the most unlimited obedience and submission to their Moorish superiors; by whom they are, in return, treated with the utmost indignity and contempt. The Moors in this, and the other states adjoining the country of the Negroes, resemble in their persons the Mulattoes of the West Indies, and scem to be a mixed race between the Moors, properly so called, of the north, and the Negroes of the fouth; possessing many of the worst qualities of both nations. Jarra is fituated in 15° 5' N. or horizontal fection of a building, exhibiting the plot Lat. and 6° 48' E. Long.

Under the generic name TANTALUS (Encycl.), we have described, after Mr Bruce, a bird which he found in Abyffinia, and concluded to be the facred ibis of ancient Egypt. M. Vaillant, during his last travels in Africa, found, in some lakes near the clepliants river, a bird very different from Mr Bruce's, which he confidered as belonging to the same species; and which he describes thus: It is three feet in height. Its head and throat, which are extremely bare, are covered with a skin of the brightest red, terminated by a band of a beautiful orange, which separates the naked part from that covered with feathers. The upper part of the wings, having broad ftripes of a fine violet colour, agreeably shaded, is bordered by a white band of feathers, the thick and filky beards of which, separated from each other, have a perfect resemblance to a rich fringe. The quills of the wings and tail are of a greenith black, which, as it receives the light in a more or less oblique direction, assumes the appearance of violet or purple. The rest of the plumage is of a beautiful white. The bill, which is long and fomewhat crooked, is yellow; as are the feet. This bird belongs to the genus of the ibis, of which we are already acquainted with feveral species.

ICE-House. See that article, Encyclopædia. Pro. fessor Beckmann, in the third volume of his History of Inventions, has proved clearly that the ancients were well acquainted with what served the purpose of ice-

houses.

"The art (fays he) of preferving fnow for cooling liquors during the fummer, in warm countries, was known in the earliest ages. This practice is mention-** Proverbs ed by Solomon*, and proofs of it are so numerous in xxv. 15. the works of the Greeks and the Romans, that it is unnecessary for me to quote them, especially as they have been collected by others. How the repositories for keeping it were constructed, we are not expressly told; but it is probable that the fnow was preferved in pits or trenches.

"When Alexander the Great besieged the city of Petra, he caused 30 trenches to be dug, and filled with fnow, which was covered with oak branches; and which kept in that manner for a long time. Plutarch fays, that a covering of chaff and coarse cloth is sufficient; and at present a like method is pursued in Portugal.

sheep pens, is thrown over it; and under these it is so well preferved, that the whole fummer through it is fent the distance of 60 Spanish miles to Lisbon.

"When the ancients, therefore, wishe I to have cooling liquors, they either drank the melted fnow, or put fome of it in their wine, or they placed jars filled with wine in the fnow, and fuffered it to cool there as long as they thought proper. That ice was also preserved for the like purpose, is probable from the testimony of various authors; but it appears not to have been used so much in warm countries as in the northern. Even at present fuow is employed in Italy, Spain, and Portugal; but in Perfia ice. I have never any where found an account of Grecian or Roman ice-houses. By the writers on agriculture they are not mentioned."

ICHNOGRAPHY, in architecture, is a transverse of the whole edifice, and of the feveral rooms and apartments in any story; together with the thickness of the walls and partitions; the dimensions of the doors, windows, and chimneys; the projectures of the columns and piers, with every thing visible in such a section.

JEBB (John), was born in Southampton street, Covent Garden, London on the 16th of February 1736. He was the eldest son of the Rev. John Jebb, dean of Cashel, in the kingdom of Ireland. He received the elements of his education in different schools, and was admitted, July 7. 1753, pensioner in the university of Dublin, whence he removed, November the 9th 1754, to St Peter's college in Cambridge, where he was likewise a pensioner. In January 1757 he proceeded to the degree of B. A. and his place in the distribution of academical honours was, on that occasion, second wrangler, the late eminent mathematician Dr Waring being the first. In 1758 he obtained the second prize of fifteen guineas, annually given by the univerfity to the authors of the best compositions in Latin prose, being senior or middle bachelors of arts. Dr Roberts, afterwards provost of Eton college, obtained the first.

In the month of June 1760, Mr Jebb was admitted probationer fellow of St Peter's college, and proceeded to the degree of Master of Arts at the commencement in the fame year; and on the first of July 1761, was confirmed fellow by Dr Mawson, bishop

of Ely.

On the 6th of June 1762, he was ordained deacon at Bugden by Dr John Green, bishop of Lincoln; and on the 25th of September, 1763, he was admitted by the same bishop into priest's orders.

On the 22d of August, 1764, Mr Jebb was collated by Dr Matthias Mawson, bishop of Ely, to the small vicarage of Gamlingay, near Potton, in Bedfordshire, upon the recommendation of Dr Law, master of Peterhouse. On the 17th of the following October, he was elected by the university into the rectory of Ovington, near Watton, in Norfolk, after a competition with the Rev. Henry Turner, then fellow of St John's college, afterwards vicar of Burwell, in Cambridgeshire. Upon casting up the votes, there appeared to be for Mr Jebb 91, for Mr Turner 73; and accordingly he was instituted into the same the 15th of December following.

On the 29th of the same month, (December 1764) Where the fnow has been collected in a deep gulph, Mr Jebb married Anne, cldest daughter of the Rev.

of Philip, fecond earl of Harborough.

Early in the year 1765, Mr Jebb, together with the Rev. Robert Thorpe, fellow of Peterhouse, and the Rev. George Woolafton, fellow of Sidney college, published, in a small quarto, a comment on those parts of Sir Ifaac Newton's Principia which more immediately relate to the fystem of the world. The title of the joint work of these able and judicious philosophers was, "Excerpta quædam e Newtoni principiis philofophiæ naturalis, cum notis variorum." A work, of which the university of Cambridge continues to bear testimo. ny to the excellence, by the general use of it in the course of academical education.

Mr Chappelow professor of Arabic, dying on the 14th of January 1768, Mr Jebb offered himself a candidate for the vacant chair; but it was given to Dr Hallifax, afterwards bishop of Gloucester; a man of deferved celebrity, of whom we regret that it was not in

our power to give a biographical sketch.

On July 10. 1769, Mr Jebb was instituted to the vicarage of Flixton, near Bungay, in Suffolk, on the prefentation of William Adair, Esq. of Flixton-hall; and on the 4th of April 1770, was inflituted to the united rectories of Homersfield and St Cross, parishes contiguous to Flixton, upon the fame prefentation: being also, in the summer of the same year, nominated chaplain to Robert earl of Harborough. In consequence of the accession of these preferments, though not confiderable in themselves, he refigned, some time in the month of October 1771, the rectory of Ovington, which he had received from the university; and Mr Sheephanks, fellow of St John's college, was elected in his place.

Dr Hallifax succeeding to the professorship of civil law, in the month of October 1770, upon the death of Dr Ridlington, Mr Jebb once more folicited that of Arabic, which Dr Hallifax then vacated: but he had by this time displayed such an innovating spirit in religion, that the univerfity gave the vacant professorship to Mr Craven, a man respected even by Mr Jebb and his friends.

Early in the year 1771, a defign was formed of applying to parliament for relief in the matter of subfeription to the liturgy, and thirty-nine articles of the Church of England; and in the profecution of this defign Mr Jebb took a very active part. He attended different meetings of the discontented clergy, held at the Feathers tavern, London, affifted in the drawing up of their petition, and wrote their circular letter, which gave to the public an account of their aims. He bufied himself at the same time in making various at tempts to bring about what he called a reformation of the univerfity of Cambridge: but finding them fruitless, he retired, on the 25th of June 1772, to Bungay, where he fludied French and Italian, and proceeded in a plan of some political or constitutional lectures.

He had by this time ccased to read the prayers of the church, though he still continued to preach occafionally; and the Archdeacon of Suffolk, holding, this the clergy. "Much altercation, (fays he) enfued; tion, and to maiatain and affert those common rights,

James Torkington, rector of Little Stukeley, in Hun- and for fome days I expected a fummons to Norwich; Jebb tingdonshire, and of lady Dorothy Sherard, daughter but have heard no more of it. I affed thus, with a view to call the attention of the Norwich clergy to our

cause; and have in part succeeded."

He acted much more honourably than this, when, in 1775, he refigned all his preferments in the church; which furely he ought not to have retained one day after his confcience would not permit him to read the prayers of the liturgy. He now resolved to become a physician; and after attending St Bartholomew's hofpital in London for fix months, as the pupil of Dr William Pitcairn, he received, on the 18th of March 1777, a diploma of Doctor of Physic from the univerfity of St Andrews!! He did not, however, commence practice till the 5th of February 1778; and even then he continued to attend the lectures of 1)r Hunter, Mr John Hunter, and Dr Higgins. On the 18th of February 1779 he was elected a Fellow of the Royal

Dr Jebb, at the breaking out of the American war, had shewn himself at Cambridge a warm partizan of the revolting colonies; and of course a keen advocate for what he called, and, we doubt not, thought, the civil liberties of mankind. He now fignalized himfelf by "An address to the Freeholders of Middlesex," affembled at Free mason's tavern in Great Queen-Hreet, on Monday, December the 20th 1779, for the purpole of establishing meetings to maintain and support the freedom of election. Upon this occasion, he communicated to James Townsend, Esq. chairman of that meeting, the above address, under the fignature of " Salus Publica;" prefuming, that if the fentiments " appeared to be founded in reason, they would not be the lefs regarded on account of their being finggested by an unknown individual."

This address was immediately printed, and very foon paffed through three editions, each being enlarged by the addition of fresh matter; and in 1782, followed the fourth edition corrected, which also bore our aux

thor's name in the title page.

About the end of February 1780, Dr Jebb was appointed by the committee of the county of Huntingdon, one of their deputies, to attend a meeting in London of representatives from certain other petitioning counties, in order to concert measures for the more exfectual reform of the present constitution of the house of commons. Soon afterwards he became one of the most active members of " the fociety for constitutional information;" of which the object, according to their own account, was to diffuse throughout the kingdom, as univerfally as possible, a knowledge of the great principles of constitutional freedom, particularly such as refpect the election and duration of the representative body. "With this view (fay they), constitutional tracts, intended for the extension of this knowledge, and to communicate it to perfons of all ranks, are printed and diffributed gratis, at the expence of the fociety. Effays, and extracts from various authors, calculated to promote the same design, are also published under the direction of the fociety, in feveral of the newspapers; year, his usual vifitation of some neighbouring parishes and it is the wish of the society to extend this knowin the church of Flixton, Mr Jebb preached fuch a ledge throughout every part of the united kingdoms, fermon against subscription, as drew upon himself a and to convince men of all ranks, that it is their intepublic rebuke from the Archdeacon, in the presence of rest, as well as their duty, to support a free constituof human nature." Could Dr Jebb have foreseen all the mischiefs which have flowed from this institution; could he have foreseen the wonderful spawn of factious focieties which have fprung from it as from a parent stock, our veneration for genius and learning will not permit us to believe, that he would have neglected the studies of his profession for the sake of taking the lead in party politics.
Dr Petit, one of the phylicians of St Bartholo-

mew's hospital, dying the 26th of May, Dr Jebb offered himself a candidate to succeed to that appointment. The election came on the 23d of June; when Dr Budd, his antagonist, succeeded by a great majority.

The opposition which was made to his election at St Bartholomew's, followed him in the winter, when he offered himself at St Thomas's hospital in the borough. Indeed he relinquished his pretensions there fooner than in the former place; but for no other reafon than because he found that all his political principles were likely to be again objected to him, and to hazard his fuccess.

In the year 1783 he concurred with others in forming "the fociety for promoting the knowledge of the scriptures," which met first on the 20th of September in that year, and whose meetings continued to be held, and, for ought we know to the contrary, are still held at Essex-house. The sketch of their plan was chiefly written by I)r Jebb; and their object was to propagate the doctrines of Unitarianism, for which he was as

great a zealot as for civil liberty.

His health now began to decline; but during his confinement, he studied the Saxon language, the Anglo Saxon laws, English history and antiquities, with a view to examine into our criminal code, and particular points of liberty. The vigour of his mind was still equal to the furnishing himself with this fresh store of knowledge; he forefaw the advantage of fuch an acquisition in the investigation of the legal rights of Englishmen, and had designed to have employed it in the support of some great constitutional questions, which he considered as essential to the freedom of his country.

But as the year began to dawn, it was very observable to many of his friends that, according to every appearance, and without fome very great and fingular effort of nature, his increased debility would defeat every exertion of the most judicious medical affistance, and terminate the remaining sparks of human life.

In this enfeebled state, his mind was active. His "Thoughts on Prifons" were printed and circulated in the county of Suffolk in 1785, by his much valued friend Mr Lofft; and there is sufficient reason for concluding that this little tract had effect on the deliberations of the justices at Ipswich and Bury, then engaged in erecting a new gaol for the division of Ipfwich, and a new house of correction for that of Bury.

The good effects of this very excellent tract, it was apprehended, would be extended by a more general publication. In this hope Dr Jebb revised and corrected it with his dying hand : and his furviving friend published it soon after his death, adding thereto " an abstract of felonies created by statute and other articles relative to the penal law.

He continued to linger till May the 2d 1786, when, about 8 o'clock in the evening, he breathed his last,

which are effential to the dignity and to the happiness leaving behind him, among men of different persuations, Jeffersonia very different characters. By the diffenters he is fel. Jerboa. dom mentioned but as the Great Jebb; by churchmen, his abilities are univerfally allowed, whilst regret is expressed that they were so often employed in support of faction and herefy. His moral character has never been aspersed.

> JEFFERSONIA, a new plant lately discovered in Georgia by Dr Brickel of Savannah, and fo named by him in compliment to the vice prefident of the United States. In the Monthly Magazine for July 1798 we have the following description of it:

JEFFERSONIA pentendria monogynia.

Calyx, below, composed of five short oval imbricated leaves; corolla, monophyllous, funnel shaped, on the receptacle, sub pentangular, bearing the filaments near the base, its margin hypocrateriform, divided into five round ducts nearly equal; flyle, pitiform, shorter than the petal, but longer than the stamens; stigma, quadripid; anthers, erect, linear, fagittated; fruit, two univalved, carinated, polyspermous capsules, united at the base, opening on their tops and contiguous fides, having flat feeds, with a marginal wing.

Only one species is as yet discovered, Jeffersonia sempervireus. It is a shrub with round polished twining steins, which climb up on bushes and finall trees; the petioles short, opposite; leaves oblong, narrow, entire, evergreen, acute; flowers axillary, yellow, having a fweet odour. The woods are full of this delightful shrub, which is covered with bloffoms for many months in the

JERBOA, see Mus, Encycl. where descriptions are given of the jaculus or common jerboa, and of the Arabian, Egyptian, and Siberian jerboas. A variety of this animal has lately been found in Canada by Majorgeneral Davies, F. R. S. and L. S. who fays it belongs to Schreber's genus of Dipus, and may be thus characterised: DIPUS CANADENSIS palmis tetradactylis, plantis pentadactylis, caudi annulata undique setosa, corpore longiore. The truth, however, feems to be, that it is only a variety, if indeed a variety, of the Siberian jerboa. The beautiful figure indeed given by General Davies of the Canadian jerboa differs in some respects from our figure of the Sibericus. Its ears lie flat and farther down the neck; its belly is not fo large; its toes are longer; and it has no brush at the end of the tail; but the habits of the two animals feem to be the same. This will be apparent from the following extracts of the General's letter to the Linnean Society:

"The first I was so fortunate to catch was taken in a large field near the falls of Montmorenci, and by its having strayed too far from the skirts of the wood, allowed myself, with the affiftance of three other gentlemen, to furround it, and after an hour's hard chafe to get it unburt, though not before it was thoroughly fatigued; which might in a great measure accelerate its

death.

" During the time the animal remained in its usual vigour, its agility was incredible for fo fmall a creature. It always took progressive leaps of from three to four, and fometimes of five yards, although feldom above 12 or 14 inches from the surface of the grass; but I have frequently observed others in shrubby places and in the woods, amongst plants, where they chiefly relide, leap confiderably higher. When found in fuch places, it is

impossible

impossible to take them, from their wonderful agility, even

and their evading all pursuit by bounding into the thickest cover they can find."

That the Canadian, as well as the Siberian Jerboa fleeps through the winter, feems evident from a fpecimen having been found, towards the end of May, inclosed in a ball of clay, about the fize of a cricket ball, nearly an inch in thickness, perfectly smooth within, and about twenty inches under ground. It was given to the Ge-

neral; who proceeds thus:

" How long it had been under ground it is impossible to fay; but as I never could observe these animals in any parts of the country after the beginning of September, I conceive they lay themselves up some time in that month, or beginning of October, when the frost becomes sharp: nor did I ever see them again before the last week in May, or beginning of June. From their being enveloped in balls of clay, without any appearance of food, I conceive they fleep during the winter, and remain for that term without fustenance. As foon as I conveyed this specimen to my house, I deposited it, as it was, in a fmall chip-box, in fome cotton, waiting with great anxiety for its waking; but that not taking place at the feason they generally appear, I kept it until I found it begin to fmell: I then ftuffed it, and preferved it in its torpid position. I am led to believe, its not recovering from that state arose from the heat of my room during the time it was in the box, a fire having been constantly burning in the stove, and which, in all probability was too great for respiration. I am led to this conception from my experience of the snow bird of that country, which always expires in a few days (after being caught, although it feeds perfectly well) if expoled to the heat of a room with a fire or stove; but being nourished with snow, and kept in a cold room or passage, will live to the middle of fummer."

JETTE, the border made round the stilts under a pier, in certain old bridges, being the same with starling; consisting of a strong framing of timber silled with stones, chalk, &c. to preserve the foundations of the piers from

injury.

JILLIFREE is a town on the northern bank of the river Gambia, opposite to James's island, where the English had formerly a small fort. The kingdom of Barra, in which it is situated, produces great plenty of the necessaries of life; but the chief trade of the inhabitants is in salt, which they carry up the river in canoes; and, in return, bring down Indian corn, cotton cloths, elephants teeth, small quantities of gold dust, &c. "The number of canoes and people constantly employed in this trade, make the king of Barra (says Mr Park) more formidable to Europeans than any other chieftain on the river, and have encouraged him to establish those exorbitant duties, which traders of all nations are obliged to pay at entry, amounting nearly to L. 20 on Suppl. Vol. I. Part II.

every vessel, great and small. These duties, or customs, Illuminatiane generally collected in person by the alkaid or governor of Jillisree, who is attended by a numerous train of noisy and troublesome dependants, who, by their frequent intercourse with the English, have acquired a smattering of our language, and beg for every thing which they fancy with such earnestness, that traders, in order to get quit of them, are frequently obliged to grant their requests. Lat. 13° 16'. Long. 16° 10' cast from Greenwich.

ILLUMINATI is the name which was assumed by Object of a fecret fociety or order, founded, on the first of May the illumi-1776, by Dr Adam Weishaupt prosessor of canon law nati. in the university of Ingolstadt. The real object of this order was, by clandestine arts, to overturn every government and every religion; to bring the sciences of civil life into contempt; and to reduce mankind to that imaginary state of Nature when they lived independent of each other on the spontaneous productions of the earth. Its avowed object, however, was very different. It proselsed to diffuse from secret societies, as from so many centres, the light of science over the world; to propagate the purelt principles of virtue; and to re-instate mankind in the happiness which they enjoyed during the golden age fabled by the poets. Such an object was well adapted to make a deep impression on the ingenuous minds of youth; and to young men alone Weishaupt at first addressed himself.

It will naturally occur to the reader, that the means of attaining this glorious object should have been made as public as possible; and that the veil of secrecy thrown over the proceedings of the order was calculated to excite suspicion, and to keep even young men of virtue and sagacity at a distance. In any other country than Germany secrecy might perhaps have had this effect; but various circumstances conspired there to make it operate

with a powerful attraction.

Ever fince free-masonry had acquired such reputation throughout Europe, a multitude of petty fecret focieties had been formed in the universities of Germany, each having its lodge, its master, its mysteries, all modelled on those founded by masons coming from England and Scotland (A). Before the foundation of Weishaupt's order, these lodges, we believe, were in general harmless; or if they were productive of any evil, it was only by giving the youth of the univerfities a taste for secrecy and mysticism. Of this Weishaupt availed himself; and as foon as he had conceived the outlines of his plan, and digested part of his system, he initiated two of his own pupils, to whom he gave the names of AJAX and TIBERIUS, affuming that of SPARTACUS to himself. These two disciples soon vying with their master in impiety (for it will be seen by and bye that he was most impious), he judged them worthy of being admitted to his mysteries, and conferred on them the high-5 E

(A) Such, we are forry to fay, is the case still. In a letter, dated the roth of May 1799, which we received from a gentleman of learning and honour then residing in Upper Saxony, is the following account of the university of Jena: "This university contains from two to three thousand students, who are almost all republicans, and go about the country in republican uniforms. They are all formed into clubs or secret societies; and the quarrel of one member of a club is taken up by all. The consequence is, that the number of duels among the different clubs is inconceivable. The weapon is generally the sabre, and the duel often ends in the death of one of the combatants." Yet gentlemen of Great Britain send their sons to Germany to be educated!

Illuminati est degree which he had as yet invented. He called them Arcopagites, denominated this monstrous affociation, THE ORDER OF ILLUMINATI, or ILLUMINEES, and in-

stalled himself GENERAL of the order.

When public report spread the news in Germany of this new order having been founded in the univerfity of Ingolftadt by Weishaupt, it was generally supposed to be one of those little college-lodges which could not interest the adepts after they had finished their studies. Many even thought that Weishaupt, who was at that time a sworn enemy to the Jesuits, had founded this lodge with no other view than to form a party for himfelf against these fathers, who after the suppression of their order had been continued in their offices of public teachers at the university of Ingolstadt; and this opinion the illuminees were at pains to propagate. His character, too, was at this time such as to remove every fuspicion from the public mind. A seeming assiduity in his duty, and a great shew of zeal and erudition in expounding the laws, eafily misled people to believe that his whole time and talents were engroffed with the fludy of them; and if we are to credit his own account, Ingolftadt had never witnessed a professor so well calculated to add new luftre to its univerfity.

Art of the founder.

This feems, indeed, to have been the general opinion as well as his own; for, fome time after the foundation of his order, he applied himself with such diligence and apparent candour to the duties of his office, that he was chosen what Abbé Barruel's translator calls SUPERIOR of the university. This new dignity only added to his hypocrify, and furnished him with fresh means of carrying on his dark defigus. He converted his house into one of those boarding houses where young men, perpetually under the eye of their masters, are supposed to be better preserved than anywhere else from the dangers which threaten them at that age. He solicited fathers and mothers to entrust their children to his care; and, counterbalancing in fecret the leffons which he was obliged to give in public, he fent home his pupils well disposed to continue the same career of seduction which he himself carried on at Ingolstadt. Attociously impious, we fee him (fays M. Barruel), in the first year of his illuminism, aping the God of Christianity, and ordering Ajax, in the following terms, to propagate the doctrines of his new gospel: " Did not Christ send his apostles to preach his gospel to the universe? You that are my Peter, why should you remain idle at home? Go then and preach."

These preachers had yet received no particular defignation; for when his first adepts were initiated, he was far from having completed the code of his order. He knew that years and experience were necessary to perfect that gradual fystem of initiations and trials which, according to the plan he had conceived, his novices were to undergo; but he could not endure the idea of facrificing years to mere theoretic projects; and he flattered himself with the hopes of supplying the deficiencies of his incomplete code by provisional regulations and private instructions, and of acquiring affociates who would receive his new gospel implicitly, and co-

operate with him in all his views.

The fect At length, however, the code was completed, and to classes of the fect divided into two grand classes; and each of these again subdivided into leffer degrees, proportionate to the Illuminate. progress of the adepts.

"The first class is that of PREPARATION. It con-preparatains four degrees, viz. those of Novice, of Minerval, of tion and Minor Illuminee, or Illuminatus Minor, and of Major Illuminee, or Illuminatus Major. To this class belong likewife fome intermediary degrees, borrowed from freemasonry, as means of propagation. Of the masonic degrees, the code of the illuminati admits the first three without any alteration; but it adapts more particularly to the views of the fect the degree of Scotch Knight, and flyles it the degree of Directing Illuminee, or Illuminatus dirigens.

The fecond class is that of the Mysteries, which The Myt. are fubdivided into the leffer and greater mysteries. The teries. leffer comprehend the priefthood, and administration of the fect, or the degrees of priesls, and of regents or princes.

In the greater mysteries are comprehended the two degrees of Magus or philosopher, and of the Man-king. The elect of the latter compose the council and degree of

"In all these classes, and in every degree (fays the Abbé Barruel), there is an office of the utmost confequence, and which is common to all the brethren. It is that which is occupied by him who is known in the Therecode by the appellation of Recruiter, or Brother Inficruiter, nuator. This (continues our author) is not a term of my invention: it is really to be found in the code, and is the denomination of that illuminee whose employment is to entice members into the fect."

As the whole strength of the order depended upon the vigilant and successful exercise of this office, some brethren were carefully instructed for it, who might afterwards visit the different towns, provinces, and kingdoms, in order to propagate the doctrines of illuminitm. Weishaupt proposed to select as his apostles either weak men, who would implicitly obey his orders, or men of abilities, who would improve the office by artifices of their own. It was, however, a duty which every brother was obliged to exercise once or twice in his life, under the penalty of being for ever condemned to the lower

I'o stimulate the ardour of the brother infinuator, he was appointed superior over every novice whom he should convert. To affish his judgment, he was instructed in three important points concerning the description of men whom he ought to felect for conversion, the means which he ought to employ for enticing them to enter the order, and the arts which he ought to study to

form their character.

To enable the recruiter to determine whom he ought To pry into select for conversion, he was to infinuate himself into to the chaall companies; he was to pry into the character of all racters of whom he should meet with, whether friends, relations, strangers, or enemies; he was to write down all his remarks regularly every day; to point out their strong and weak fides, their paffions and prejudices, their intimacies, their interests, and their fortune. This journal was to be transmitted twice every month to the superiors; by which means the order would learn who were friendly or hostile to their views, and who were the individuals to whom they ought to direct their arts of feduction (B).

I minati.

] [ons

per for

The persons to be excluded were all such as would expose the order to suspicion or reproach. All indiscreet talkers, all who were proved violent, and difficult to be managed, all addicted to drunkenness, and all Pagans, Jews, and Jesuits, were to be rejected. As the patronage of princes would tend much to enrich and strengthen the fociety, it was agreed to admit them to the inferior degrees, but they were never to be initiated into the grand mysteries; they were never to rise beyond the degree of Scotch knight.

The persons to be selected were young men of all stations, from eighteen to thirty; but particularly those whose education was not completed, and consequently whose habits were not formed. "Seek me out (fays Weishaupt in his directions to the infinuator) the dexterous and dashing youths. We must have adepts who are infinuating, intriguing, full of refource, bold and enterprising; they must also be flexible and tractable, obedient, docile, and sociable." In another place he says, " Above all things pay attention to the figure, and felect the well made men and handsome young fellows. They are generally of engaging manners and nice feelings. When properly formed, they are the best adapted for negociations; for first appearances prepossels in their favour. It is true, they have not the depth that men of more gloomy countenances often have. They are not the persons to be entrusted with a revolt, or the care of sirring up the people; but it is for that very reason we must know how to choose our agents. I am particularly fond of those men whose very foul is painted in their eyes, whose foreheads are high, and whose countenances are open. Above all, examine well the eyes, for they are the very mirrors of the heart and foul. Observe the look, the gait, the voice. Every external appearance leads us to distinguish those who are fit for our school."

Though young men were preferred, yet persons of all ages were to be admitted if their character accorded with the principles of the order. The infinuator was defired to feek out those who were diftinguished by their power, riches, or learning. " Spare no pains (fays Weishaupt), spare nothing in the acquisition of such adepts. If heaven refuse its succour, conjure hell.

Fledere si nequeas superos, Acheronta moveto."

Persons were to be singled out from those professions which give men influence over others, or put them in the most favourable situation for disseminating any peculiar opinions. With this view, schoolmasters, and superintendants of ecclesiastic seminaries, were to be sought after with much care. Booksellers, post masters, and the secretaries of post-offices were also to be selected. Those professions which accustomed men to speak and argue, as that of counsellors and attorneys, and even phyficians, were also to be courted. "They are worth having (fays Weilhaupt), but they are sometimes real devils, fo difficult are they to be led; they are, however, worth having when they can be gained over." Every exertion was to be made to gain the officers of a prince, whether prefiding over provinces or attending him in his councils. " He that has done this, has done more than if he had engaged the prince himself."

There was also another description of men of whom Weishaupt very wisely judged that they would be admirably fitted for the diffution of his doctrines. These were the disappointed and disfatisfied. " Select those in particular (fays he) who have met with misfortunes, not from accidents, but from some injustice; that is to fay, in other words, the discontented; for such men are to be called into the bosom of illuminism as into their

proper afylum.

When the infinuator has made choice of his victim, And their he is required to draw from his diary a view of his cha-characters racter, opinions, principles, and connections. This he transmitted is to transmit to the superiors for their examination, and riors. that they may compare it with the diaries which they have already received, perhaps from different infinuators. When the choice of the infinuator is approved, the fuperiors determine which of the infinuators will be belt qualified to perform the task of seducing their candidate.

Two different methods were recommended; one of which was to be employed in enticing men who were fomewhat advanced in life or diffinguished by science; the other was to be used in seducing young men whose

character was not formed.

5 E 2 With

for propagating their principles, we shall give the character of Zwack, denominated Cato, as it is described in the tablet of his infinuator Ajax (Massenhausen).

" Francis Xaverius Zwack was son of Philip Zwack, commissary of the Chambre des Comptes, and was born at Ratisbon; at the time of his initiation (29th May 1776) he was twenty years of age, and had finished his col-

"He was then about five feet high; his person emaciated with debauchery; his constitution bordering on melancholy; his eyes of a dirty grey, weak and languishing; his complexion pale and fallow; his health weak, and much hurt by frequent diforders; his nofe long, crooked and hooked; his hair light brown; gait precipitate;

his eyes always cast towards the ground; under the nose, and on each side of the mouth, a mole.

"His heart tender and philanthropic in an extraordinary degree; but stoic when in a melancholy mood; otherwife a true friend, circumspect, reserved, extremely secret; often speaking advantageously of himself; envious of other people's perfections; voluptuous; endeavouring to improve himself; little calculated for numerous assemblies; choleric and violent, but easily appealed; willingly giving his private opinions when one has the precaution to praise him, though contradicting him; a lover of novelties. On religion and conscience widely differing from the received ideas; and thinking precifely as he ought, to become a good member of the order.

"His predominant passions are, pride, love of glory, probity; he is easily provoked; has an extraordinary propensity for mysteries; a perpetual custom of speaking of himself and of his own perfections; he is also a perpensity for mysteries. fect master in the arts of dissimulation; a proper person to be received into the order, as applying himself particularly to the study of the human heart." Such is the character of the beloved disciple of Weishaupt, the in-

comparable Cato, and a leader of the fect of the illuminees!

iced by natever eans;

With men of knowledge, who had already imbibed ring in his closet a new constitution for the world; and Illuminate. the principles of modern philosophism (for no true phi-Proper me. losophers were to be attempted), the infinuator was to thods of fe-assume the character of a philosopher well acquainted ducing men with the mysteries of ancient times. He was to descant

upon the importance of the secret doctrines transmitted by tradition, to quote the gymnosophists of India, the priests of Isis in Egypt, and those of Eleusis, with the Pythagorean school in Greece. He was to learn by heart certain passages from Isocrates, Cicero, and Seneca, that he might have them ready upon all occafions. He was to throw out hints, that these secret doctrines explained the difficult questions concerning the origin and order of the universe, the Providence of God, the nature of the foul, its immortality and future destination; he was to inspire them with the belief that the knowledge of these things would render life more agreeable and pain more supportable, and would enlarge their ideas of the majesty of God: he was then to declare that he had been initiated into these mysteries. If the candidate expressed any curiosity to be made acquainted with them, the infinuator was first to ascertain his opinions upon fome leading points, by proposing to him to write a differtation upon certain questions. Should the answers not please the infinuator, he was to relinquish his prey; but should they be satisfactory, the candidate was to be admitted to the first degree.

men,

When the felected victim was young, and had not im-And young bibed any of those opinions which corresponded with the principles of the fect, a different method was to be followed. " Let your first care (says the legislator to his infinuators) be to gain the affection, the confidence, and the esteem of those whom you are to entice into the order. Let your whole conduct be fuch, that they shall furmise something more in you than you wish to shew; hint, that you belong to some secret and powerful society; excite by degrees, and not at once, a wish in your candidate to belong to a fimilar fociety. Certain arguments and certain books, which the infinuator must have, will greatly contribute to raife fuch a wish; fuch, for example, are those which treat of the union and

> strength of affociations." Every infinuator must be provided with books of this fort. But that their fuccess might not depend solely upon books, Weishaupt gave to his disciples a specimen of the artifices which they might employ. The infinuator might begin by observing, that a child in the cradle, abandoned to itself, is entirely helpless; and that it is by the affiftance of others that it acquires strength; and that princes owe their greatness and their power to the union of their subjects. 'Then the infinuator might touch on the importance of knowing mankind, and the arts of governing them; that one man of parts might eafily lead hundreds, even thousands, if he but knew his advantages. He was next to dwell upon the defects of civil fociety; to mention how little relief a man can obtain even from his best friends; and how very necessary it is for individuals to support one another in these days: to add, that men would triumph even over heaven were they but united. He was to adduce as examples, the influence of the freemasons and of the Jesuits. He was to affert, that all the great events which take place in the world depend upon hidden causes, which these societies powerfully influence. He was to awake in the breaft of his pupil the defire of reigning in fecret; of prepa-

of governing those who think they govern others.

After these, or other artifices of the same kind, have into the no-

been employed, if the candidate be inspired with an ar-viciate. dour to be initiated, and give fatisfactory answers to the questions proposed to him, he is immediately admitted a novice. But should he reject all means of seduction, let him take heed to himself; " for the vengeance of fecret focieties is not a common vengeance; it is the hidden fire of wrath. It is irreconcileable; and scarcely ever does it cease the pursuit of its victims until it has feen them immolated."

The period of the noviciate varied according to the Period of age of the new convert to illuminism. At first it con the novi-tinued three years for those under eighteen years of age, two years for those between eighteen and twenty. four, and one year for those who were near thirty; but

it was afterwards shortened.

The novice was not acquainted with any of the order except his infinuator, under whose direction he remained during his noviciate. The first lessons which he was taught respected the inviolable nature of the secrecy which every illuminee was obliged to observe. He was told that filence and fecrecy were the very foul of the order; that ingenuousness was a virtue only with respect to his superiors; and that distrust and reserve were fundamental principles. He was enjoined never to speak of any circumstance relating to the order, concerning his own admission, or the degree which he had received, not even before brethren, without the strongest necessity; and was required to fign a declaration to this purpose.

The novice was next taught the dictionary of the or. Dictionary, der, its geography, calendar, and cypher. To prevent geography, the possibility of discovery, every illuminee received a and cyphes new name, which was characteristic of his dispositions, of theoror of the services which were expected of him. Thus der. Weishaupt, as we have observed, was called Spartacus, because he pretended to wage war against those oppresfors who had reduced mankind to flavery; and Zwack, as we have feen, was named Cato, because he had written a differtation in favour of suicide, and had once

determined to commit that crime.

According to the new geography of the order, Bavaria was called Achaia; Munich was called Athens; Vienna was named Rome; Wurtzburg was denominated Carthage; and Ingolitadt, the fountain of the order, was called Ephejus, and by the profound adepts. Eleufis. The novice had also to learn the Persian calendar, which the order had adopted. Their era began A. D. 630. The months received new names: May was called Adarpahascht; June, Chardad; July, Thermeh; August, Merdedmeh; and so on. The cypher confifted of numbers which corresponded to the letters of the alphabet, in this order a, b, c, d, answering to the numbers 12, 11, 10, 9.

The novice had next to study the statutes of the illuminees, which he was affured contained nothing injurious to the state, to religion, or to good morals. He was next defired to apply himself to acquire the morality of the order; which he was to do, not by reading the gospels, but by perusing Epictetus, Seneca, and Antoninus, and by studying the works of the modern fophists Weiland, Meiners, and Helvetius, &c. ftudy of man was also recommended as the most interest-

dr his

ov cha-

merely as a science, but as an art. A model of a journal was given him, and he was required to infert in it observations upon the character of every person that he happened to meet with. To quicken his diligence, the infinuator occasionally examined his journal. In the mean time the infinuator was watching him as a centinel, and noting down regularly observations upon the defects and merits of his pupil, which he always fent to

his superiors.

The great object of the infinuator was to entangle the novice, and to bind him indiffolubly to the order. With this view he required the novice to draw a faithful picture of himself, under the pretence that he would thus know himself better. He desired him to write down his name, his age, his country, his residence, and his employment; to give a lift of the books in his library; to state his revenue; to enumerate his friends and enemies, and the cause of his enmities. He was also to give a fimilar account of his father and mother, his brothers and fifters, and to be very careful in pointing out their passions and prejudices, their strong and weak sides.

In the mean time, the infinuator was occupied in drawing up a new statement of every thing he had been able to discover of the character and conduct of the novice. This statement was transmitted to the superiors, and compared with the former. If the novice was approved, he was then admitted to the fecond degree, upon his anfwering, in a fatisfactory manner, twenty four grand questions, which might enable the order to judge of his principles and the credit to which he was entitled, and would fix him down by stronger ties to the authority of the superiors. The detestable principles of the illuminees now begin to appear, as will be evident from the following questions which we have selected:

Have you feriously reflected on the importance of the step you take, in binding yourself by engagements that are unknown to you? Should you ever discover in the order any thing wicked or unjust to be done, what part would you take? Do you, morcover, grant the power of life and death to our order or fociety? Are you disposed, upon all occasions, to give the preference to ned by men of our order over all other men? Do you subject 1 fociety. yourself to a blind obedience, without any restriction what-

The novice having thus furrendered his conscience, his will, and his life, to the devotion of the conspirators, and thus subscribed, with his own hand, and confirmed by his oath, a refolution to become the most abject flave, was now deemed qualified to afcend to the fecond

degree, called Minerval.

In the dead hour of midnight he was conducted to a retired apartment, where two of the order were waiting nission to receive him. The fuperior, or his delegate, appearof Mi ed standing in a severe and threatening posture; he held a glimmering lamp in his hand, and a naked fword lay before him. The novice was asked, whether he still perfifted in his intention of adhering to the order? Upon answering in the affirmative, he was ordered into a dark room, there to meditate in filence on his refolution. On his return, he was strictly and repeatedly questioned if he was determined to give implicit obedience to all the laws of the order? The infinuator became fecurity for his pupil, and then requested for him the protection of the order, which the fuperior granted with great folem.

mu nati. ing of all the sciences. He was taught this study not nity, protesting that nothing would be found there hurt-Illuminati. ful to religion, to morals, or to the state. Having thus faid, the superior takes up the naked sword, and pointing it at the heart of the novice, threatens him with the fatal consequences of betraying the secrets of the order. The novice again takes an oath, by which he binds himself, in the most unlimited manner, to serve the order with his life, honour, and estate, and to observe an inviolable obedience and fidelity to all his fuperiors. He is then admitted a Minerval, and henceforth is allowed to attend the academy of the fect.

The Minerval academy was composed of 10, 12, or Minerval 15 Minervals, and placed under the direction of a ma-academy;

jor Illuminee. It met twice every month in an inner apartment, separated from the other rooms of the manfion by an antichamber; the door of which was to be thut with care during the meeting, and fliongly fecured by bolts. At the commencement of every meeting, the prefident read and commented upon fome felect passages of the Bible, Seneca, Epictetus, Marcus Aurelius, or Confucius; evidently with a view of diminishing the reverence for the facred writings, by thus placing them on a level with the heathen moralists. Then each brother was asked what books he had read fince last meeting, what observations he had made, and what fervices he had performed for promoting the fuccess of the order?

To each Minerval academy a library belonged. This Its library was formed by the contributions of the brethren, by presents of books, and by another method very extraordinary. All Illuminees acting as librarians, or keepers of archives, were admonished to steal such books or manuscripts as might be useful to the order. At one time, fending a lift of the books which he wished to be embezzled from the library of the Carmes, Weishaupt says, "All these would be of much greater use if they were in our hands. What do those rascals

do with all these books?"

Every brother at his admission was required to declare to what art or science he meant chiefly to apply; and it was expected, that he should afterwards every year give an account of the discoveries or improvements which he had made. All the other brethren who were occupied in the fame studies, were desired to give him every poffible affiftance. 'I hus a kind of academy was formed, to which those who could not serve it by their talents. might give pecuniary contributions. That this academy might have the appearance of a literary fociety, prizes were annually distributed; the best discourse was published, and the profits fent to the coffers of the or-

Every month the president was to take a review of the faults which he had observed in his pupils, and examine them concerning those which they might have been conscious of in themselves; and it would be an unpardonable neglect, fay the statutes, should any pupil pretend, that during the space of a whole month he had remarked nothing reprehensible.

It is impossible to read these rules without admiring them. Were men but half as anxious, attentive, and careful, to render themselves good citizens and good men, as these men were to render themseves successful Admissions conspirators, what a bleffed world should we see!

The Minerval was rigorously scrutinized, whether he gree of miswas ready to submit to every torture, or even to com-nor illumia, mit nec.

trained for

the degree

Illuminati mit suicide, rather than give any information against the and demonstrate how necessary secret societies are for thumination order. Suicide was reckoned not only innocent, but honourable, and was also represented as a peculiar species of voluptuousness. In order to discover the fentiments of the Minervals upon this subject, they were required to write a differnation upon the character and death of Cato, or any fimilar subject. They were also defired to discuss the favourite doctrine of Weishaupt, that the end fanctifies the means; a principle of the most pernicious tendency, which would render calumny, affaffination, sedition, and treason, laudable and excellent. Next, they were called upon to compose a differtation, by which their opinions concerning kings and priefts might be ascertained. If they performed all these tasks with the spirit of an infidel, and the desperate firmness of a conspirator, they were then judged worthy of being promoted to the degree of minor illuminee.

The minor illuminees held meetings fimilar to those

of the Minerval academy. It was necessary that the prefident should be one who was raised to the degree of Minor illu-prieft, and initiated in the mysteries; but he was required to persuade his pupils, that beyond the degree which he had attained there were no mysteries to be disclosed. The minor illuminees were to be so trained, that they might look upon themselves as the founders of the order; that by this powerful motive they might be animated to diligence and exertion. With this view, hints were scattered rather than precepts enjoined. It was infinuated, that the world was not fo delightful as it ought; that the happiness for which man was made

is prevented by the misfortunes of some, and the crimes of others; that the wicked have power over the good; that partial infurrection is useless; and that peace, contentment, and fafety, might be easily obtained by means

drawn from the greatest degree of force of which human nature is capable. Such views, it is added, actuating a fecret fociety, would not only be innocent, but

most worthy of the wife and well-disposed.

Weishaupt had formed, with peculiar care, a code for this degree, which was intitled Instructions for forming useful Labourers in Illuminism. These instructions discover an astonishing knowledge of human nature, and are drawn up with a degree of systematic coolness which perhaps no conspirator before him ever exhibited. He lays down rules, by which the character of almost any person may be ascertained. He recommends to the minor illuminees, to attend to the conduct of any perfon entrusted to their care, at two periods; when he is tempted to be what he ought not to be, and when, removed from the influence of every external temptation, he follows the dictates of his inclination. They were to fludy the peculiar habits and ruling passions of each; to kindle his ardour by descanting on the dignity of the order, and the utility of its labours; to infuse a spirit of observation, by asking questions, and applauding the wildom of the answers; to correct the failings of their pupil, by speaking of them as if they were not his, and thus making him judge in his own cause; to instruct and advise, not by tedious declamation, but by fometimes dropping a few words to the purpose, when the mind should be in a proper state to receive them. Above all, they were directed to avail themselves of those moments when they observed a pupil discontented with the world. " It is then (fays Weishaupt) you must press the swelling heart, stimulate the sensibility,

the attainment of a better order of things."

Having passed with applause through the states of 23 probation already described, the minor illuminee is vice. promoted to the rank of major illuminee, or Scotch novice. As major illuminee, he is encompassed with more rigid chains; and as Scotch novice, he is difpatched as a missionary into masonic lodges, to convert the brethren to illuminism.

The candidate for this degree is strictly examined, in order to discover what opinions he now entertains concerning the object of the fociety; the motives that prompted him to join it; whether he is disposed still to co-operate with the rest of the brethren in accomplishing the grand object; and whether he be a member of any other fociety; and what are the duties which it re-

The fertile genius of Weishaupt is not exhausted; he has still in referve artifices more profound, and bonds more powerful; his refources keep pace with the progress of his schemes. He now lays a snare for his pupils, from which he hopes none can escape, and therefore he flatters himself they are his for ever. He de-Candidates mands of every candidate for higher degrees, to write, for higher as a proof of confidence, a minute and faithful account degrees of his whole life, without any referve or diffimulation. fubmit to Referve or diffimulation would indeed be vain; for the new trials. most fecret eircumstances of his life are already well known to the adepts, by means of innumerable spies. who, by the appointment of the superiors, have, unknown to him, been watching and fcrutinizing all his actions and words, his temper, passions, and opinions.

Now is presented to the candidate the code of the brother scrutator, called by the order the nosce te ipsum (know thyself). This is a catechism, containing from a thousand to fifteen hundred questions, concerning his person, his health, his education, his opinions, his inclinations, his habits, his passions, his prejudices, and even his weaknesses. Questions are also proposed respecting his acquaintances, his relations, friends, and ene-The candidate is required to enumerate his favourite colours, to describe his language, the nature of his conversation, his gait and gestures. Nothing, in fhort, is omitted that can tend to diftinguish his character as an individual, or as a member of fociety. Upon many qualities in his character, thirty, forty, or fometimes near a hundred questions are proposed. following specimen will enable the reader to judge what aftonishing care Weishaupt employed to discriminate characters.

Is his gait flow, quick, or firm? Are his steps long, fhort, dragging, lazy, or skipping? Is his language regular, diforderly, or interrupted ? In speaking, does he agitate his hands, his head, or his body with vivacity? Does he close upon the person he is speaking to? Does he hold him by the arm, clothes, or button-hole? Is he a great talker, or is he taciturn? If so, why? Is it through prudence, ignorance, respect, or sloth? &c. Concerning his education, he is questioned to whom does he owe it? Has he always been under the eyes of his parents? How has he been brought up? Has he any esteem for his masters? Has he travelled, and in what countries?

By these questions his temper and dispositions might be accurately known. His leading paffions would be

himself with different parties, which does he adopt; the ftrongest or the weakest; the wittiest or the most stupid? Or does he form a third? Is he constant and firm in spite of all obstacles? How is he to be gained? by praise, by flattery, or low courtship; by women, money, or the entreaties of his friends? Does he love fatire; and on what does he exercise that takent? on religion, hypocrify, intolerance, government, ministers,

All these questions are to be answered and illustrated by facts. It is necessary to observe, that the scrutators also give in written answers to all these questions. When the candidate has thus given a minute history of his life, and revealed all his fecrets, his foibles, his errors, his vices, and his crimes, Weishaupt triumphantly exclaims, " Now I hold him; I defy him to hurt us; if he should wish to betray us, we have also his se-

crets."

The adept is next introduced into a dark apartment, where he folemnly swears to keep secret whatever he may learn from the order. He then delivers up the history of his life, sealed, when it is read to the lodge, and compared with the character drawn of him by the brother scrutators. A corner of the veil is now lifted up, still, however, with extreme caution. Nothing appears palpable but the pureft principles and most generous defigns. At the fame time many things are darkly fuggested, which are incompatible with purity and generolity; for while the utmost care is employed to deceive the understanding, nothing is neglected that can tend secretly to corrupt the heart. A number of questions are asked; the evident intention of which is to make the adept discontented with the present moral government of the world, and to excite the defire of attempting a great revolution. After answering these questions, the secretary opens the code of the lodge; and having informed the young illuminee that the objest of the order is to diffuse the pure truth, and to make virtue triumph, he proceeds to show that this is to be accomplished by freeing men from their prejudices, and enlightening their understandings. attain this, (continues the fecretary), we must trace the origin of all sciences, we must reward oppressed talents, we must undertake the education of youth; and, forming an indiffoluble league among the most powerful geniuses, we must boldly, though with prudence, combat superstition, incredulity, and folly; and at length form our people to true, just, and uniform principles on all subjects." The secretary adds, that in attempting to divest vice of its power, that the virtuous may be rewarded even in this world, the order is counteracted by princes and priests, and the political constitutions of nations; that, however, it was not intended to excite revolutions and oppose force by force, but merely to bind the hands of the protectors of disorder, and to govern without appearing to command; that the powers of the earth must be encompassed with a legion of indefatigable men, all directing their labours towards the improvement of human nature. Were there but a certain number of fuch men in every country, each might form two others. "Let these (says he) only be united, and nothing will be impossible to our order." All this is very specious; it is well contrived to fasciwate the imagination of the young, and the heart of

Ill inati. discovered by the following queries. "When he finds the generous and benevolent, while, under all this pre-Illuminatitended regard to virtue and to the happiness of mankind, is concealed a most formidable conspiracy against the peace of the world.

After this address is delivered, the major illuminee is prefented with the codes of the infinuator and fcrutator; for he must now inspect the pupils of the insinuators, and must exercise the office of scrutator while

presiding over the Minerval academies.

The next degree, which is that of Scotch knight, The degree is both intermediate and stationary. It is stationary knight for those who are not sufficiently imbued with the principles of the order, and intermediate for those who have imbited the true spirit of illuminism. The Scotch knights were appointed the directors of all the preparatory degrees, and to watch over the interests of the order within their diffrict. They were to study plans for increasing the revenues of the order, and to endeavour to promote to public offices of confidence, of power and wealth, as many of the adepts as possible; and to strive to acquire an absolute sway in the mafonic lodges. They were to procure the management of the masonic funds; and while they were to persuade the brethren that thefe were expended according to their own orders, they were to employ them for promoting the views of the order. Thus one office of the

virtue triumph. After passing with applause through this long and tedious probation, the adept is introduced to the class of the mysteries. He is not yet, however, made acquainted with the whole secrets of the society; he must still submit to new trials; his curiosity must be farther excited, his imagination must be kept longer upon the stretch, and his principles of depravity be rendered more violent and inveterate before the vail be entirely withdrawn, which will discover to him Weishaupt and his infernal crew, plotting the destruction of the laws, sciences, and religion of mankind. The degree of epopt or prieft, to which the adept was next raifed, opened to view, however, fo great a part of the myf-

Scotch knights was to embezzle the money that was

entrusted to them, in order to diffuse truth, and to make

teries, that the reader will be fully prepared to expect the fecrets which remain to be unfolded in the other

Before being admitted to the degree of epopt, the Preparaadept was required to give a written answer to ten pre-tions for liminary questions. The infinuations against the esta-the priest-blished order of the world, which had formerly been hood. blished order of the world, which had formerly been flightly mentioned, increase now to an indirect propo-fal to attempt a complete revolution. The candidate is asked, whether he thinks the world has arrived at that happy flate which was intended by nature? Whether civil affociations and religion attain the ends for which they were defigued? Whether the sciences are conducive to real happiness? or whether they are not merely the offspring of the unnatural flate in which men live, and the crude inventions of crazy brains? It is then proposed as a question, whether there did not in antient times exift an order of things more simple and happy? What are the best means for restoring mankind to that state of felicity? Should it be by public measures, by violent revolutions, or by any means that would ensure success? Would it not be proper, with this view, to preach to mankind a religion more per-

Illuminatil feet, and a philosophy more elevated? And, in the meantime, is it not advisable to disseminate the truth in fecret focieties?

> Should the answers given to these questions accord with the fentiments of the order, on the day fixed for the initiation, the candidate is blindfolded, and, along with his introducer, is put into a carriage, the windows of which are darkened After many windings and turnings, which it would be impossible for the adept to trace back, he is conducted to the porch of the temple of the mysteries. His guide strips him of the masonic infignia which he wore as a knight, removes the bandage from his eyes, and prefents him with a drawn fword; and then having flrictly enjoined him not to advance a step till he is called, leaves him to his meditations. At length he hears a voice exclaiming, "Come, enter, unhappy fugitive; the fathers wait for you; enter, and shut the door after you." He advances into the temple, where he fees a throne with a rich canopy rifing above it, and before it, lying upon a table, a crown, a fceptre, a fword, fome pieces of gold, and precious jewels, interlaid with chains. At the foot of the table, on a scarlet cushion, lic a white robe, a girdle, and the simple ornaments of the facerdotal order. The candidate is required to make his choice of the attributes of royalty, or of the white robe. If he chuse the white robe, which he knows it is expected he should do, the hierophant, or instructor, thus addresses him: "Health and happiness to your great and noble foul. Such was the choice we expected from you. But stop; it is not permitted you to invest yourfelf with that robe until you have heard to what we now destine you." The candidate is then ordered to fit down; the book of the mysteries is opened, and the whole brethren liften in filence to the voice of the hierophant.

The exordium is long and pompous; much artifice previous to is concealed in it, and much eloquence displayed. It admission. expatiates on the sublime and generous views of the socicty; evidently with the defire of lulling afleep the fuspicion of the candidate, of exciting him to admiration, and of inspiring him with enthusiasm. The hierophant then proceeds to unveil the mysteries. He launches out into a splendid description of the original state of mankind; when health was their ordinary state, when meat, and drink, and shelter, were their only At that period (fays he) men enjoyed the most incstimable blessings, equality and liberty; they enjoved them to their utmost extent: but when the wandering life ccased, and property started into existence; when arts and fciences began to flourish; when a diftinction of ranks and civil affociations were established, "liberty was ruined in its foundation, and equality difappeared. The world then ceased to be a great family, to be a fingle empire; the great bond of nature was rent afunder." Wants now increased, and the weak imprudently submitted to the wife or the strong, that they might be protected. As the submission of one person to another arises from wants, it ceases when the wants no longer exist. Thus the power of a father is at an end when the child has acquired his strength. Every man, having attained to years of diferction, may govern himfelf; when a whole nation, therefore, is arrived at that period, there can exist no farther plea for keeping it in wardship.

Such a state as that of civil fociety, is then repre- Illumination fented as incompatible with the practice of virtue, "With the division of the globe, and of its states, benevolence (fays the hierophant) was restrained within certain limits, beyond which it could no longer be extended. Patriotism was deemed a virtue; and he was styled a patriot who, partial towards his countrymen, and unjust to others, was blind to the merits of strangers, and believed the very vices of his own country to be perfections. We really beheld (continues he) patriotism generating localism, the confined spirit of families, and even egoism. Diminish, reject that love of country, and mankind will once more learn to know and love each other as men. Partiality being cast aside, a union of hearts will once more appear, which will expand itself over the globe."

These unphilosophical declamations, enthusiastically pronounced, at length make the profelyte exclaim, in unifon with his mafter, " Are fuch then the confequences of the institution of states, and of civil society? O folly! Oh people! that you did not foresee the sate that awaited you; that you should yourselves have seconded your despots in degrading human nature to servitude, and even to the condition of the brute!"

Having wrought up the profelyte to this pitch of frenzy, and enumerated all the evils which, according to Weishaupt, arise from political affociation, the hierophant comes to reveal the means by which the grievances of the human race may be redreffed. "Providence (he fays) has transmitted the means to us of secretly meditating, and at length operating, the falvation of human kind. These means are the secret fchools of philosophy. These schools have been in all ages the archives of nature, and of the rights of man. These schools shall one day retrieve the fall of human nature, and PRINCES AND NATIONS SHALL DISAPPEAR FROM THE FACE OF THE FARTH; and that without any violence. Human nature shall form one great family, and the earth shall become the habitation of the man of reason. Reason shall be the only book of laws, the fole code of man. This is one of our grand mysteries. Attend to the demonstration of it; and learn how it has been transmitted down to us."

This pretended demonstration makes part of the same fophistical harangue; and confists in panegyrics on the dignity of human nature; in a baseless morality; and in a fcandalous perversion of the Christian, scriptures, with a blasphemous account of the ministry of the Saviour of the world.

"What strange blindness (continues the hierophant) can have induced men to imagine, that human nature was always to be governed as it has hitherto been? Where is the being, who has condemned men, the best, the wifest, and the most enlightened men, to perpetual flavery? Why should human nature be be-reft of its most perfect attribute, that of governing itself? Why are those persons to be always led who are capable of conducting themselves? Is it then impossible for mankind, or at least the greater part of them, to come to majority? Are we then fallen fo low as not even to feel our chains, as to hug them, and not cherish the flattering hope of being able to break them, and recover our liberty? No; let us own that it is not impossible to attain UNIVERSAL INDEPENDENCE."

The principal means which Weishaupt offers to his

1 ninati. adepts for the conquest of this land of promise, is to diminish the wants of the people; and accordingly the T illumi-code denounces eternal war with every species of commerce. Hence the hierophant proceeds to inform the candidate, that he who wishes to subject nations to merce. his yoke, need but to create wants, which he alone can fatisfy. "Confer (fays he) upon the mercantile tribe fome rank or some authority in the government, and you will have created perhaps the most formidable, the most despotic of all powers. He, on the contrary, who wishes to render mankind free, teaches them how to refrain from the acquisition of things which they cannot afford: he enlightens them, he infuses into them bold and inflexible manners. If you cannot diffuse, at the same instant, this degree of light among all men, at least begin by enlightening yourself, and by rendering yourself better. The mode of diffusing universal light is, not to proclaim it at once to the whole world, but to begin with yourself; then turn to your next neighbour: you two can enlighten a third and a fourth: let these in the same manner extend and multiply the number of the children of light, until numbers and force shall throw power into your hands. You will foon acquire sufficient force to bind the hands of your opponents, to subjugate them, and to stifle wickedness in the embryo;" i. e. you will foon be able to stifle every principle of law, of government, of civil or political fociety, whose very institution, in the eyes of an illuminee, is the germ of all the vices and misfortunes of human naeir mo-

The hierophant, continuing to infift on the necessity of enlightening the people to operate the grand revolution, feems to be apprehensive that the candidate may not yet clearly conceive the real plan of this revolution, which is in future to be the fole object of all his instructions. Let your instructions and lights be univerfally diffused; so shall you render mutual fecurity universal; and security and instruction will enable us to live without prince or government. The instruction which is to accomplish this great end, is instruction in morality, and morality alone; for "true morality is nothing else than the art of teaching men to Shake off their wardship, to attain the age of manhood; and thus to need neither princes nor governments. The morality which is to perform this miracle, is not a morality of vain subtleties. It is not that morality which, degrading man, renders him careless of the goods of this world, forbids him the enjoyment of the innocent pleafures of life, and inspires him with the hatred of his neighbour. Above all, it must not be that morality which, adding to the miferies of the miferable, throws them into a state of pusillanimity and despair, by the threats of hell and the fear of devils. It must be a divine doctrine, fuch as Jesus taught to his disciples, and of which he gave the real interpretation in his fecret conferences."

The impious hierophant then proceeds, with matchhemies of less blasphemy, to represent the Redeemer of mankind as teaching, like the Grecian fophists, an exoteric and an esoteric doctrine. He describes him as the grand master of the illuminees; and affirms, that the object of his fecret, which is loft to the world in general, has been preferved in their mysteries. It was "to reinstate mankind in their ORIGINAL EQUALITY and LI-BERTY, and to prepare the means. This explains in

SUPPL. VOL. I. Part II.

what fense Christ was the Saviour and Redeemer of the Illumination world. The doctrine of original fin, of the fall of man, and of his regeneration, can now be understood. The state of pure nature, of fallen or corrupt nature, and the state of grace, will no longer be a problem. Mankind, in quitting their state of original liberty, fell from the state of nature, and lost their dignity. In their civil fociety, under their governments, they no longer live in the state of pure nature, but in that of fallen and corrupt nature. If the moderating of their pais fions, and the diminution of their wants, reinstate them in their primitive dignity, that will really conflitute their redemption and their flate of grace. It is to this point that morality, and the most perfect of all morality, that of Jesus, leads mankind. When at length this doctrine shall prevail throughout the world, the reign of the good and of the elect shall be established."

This language (as M. Barruel observes) is surely not enigmatical; and the profelyte who has heard it without shuddering, may flatter himself! with being worthy of this Antichristian priesthood. He is led Preparaback to the porch, where he is invested with a white tory rites to tunic and broad fearlet belt of filk. The fleeves of the tunic, which are wide, are tied in the middle and at the extremities with ribbons likewife of scarlet; and the candidate is recalled into the temple of mysteries. He is met by one of the brethren, who does not permit him to advance till he has declared " whether he perfectly understands the difcourfe which has been read to him; whether he has any doubts concerning the doctrines taught in it; whether his heart is penetrated with the fanctity of the principles of the order; whether he is fenfible of the call, feels the strength of mind, the fervent will, and all the difinterestedness requisite to labour at the grand undertaking; whether he is ready to make a facrifice of his will, and to fuffer himself to be led by the most excellent Superiors of the order."

The rites of the preceding degree were in impious de- Initiation to rision of the facrament of the Lord's supper; those of the the priestpresent are an atrocious mimicry of sacerdotal ordination; hood. at which, as every one knows, the Lord's supper is likewise celebrated. A curtain is drawn, and an altar appears with a crucifix upon it. On the altar is a bible; and the ritual of the order lies on a reading desk, with a censer and a phial sull of oil beside it. The dean, or president, who acts the part of a bishop, blesses the candidate, cuts hair from the crown of his head, anoints him, clothes him in the vestments of the priesthood, and pronounces prayers after the fashion of the order. He presents him with a cap, saying, "Cover thyself with this cap; it is more precious than the royal diadem." The mock communion is then diffributed; and it confifts of milk and honey, which the dean gives to the profelyte, faying, "This is that which nature gives to man. Reflect how happy he would still have been, if the defire of superfluities had not, by depriving him of a taste for such simple food, multiplied his wants, and poisoned the balm of life." The ceremonies are terminated by delivering to the epopt that part of the code which relates to his new degree.

Among the instructions which it contains, the fol-Duties of lowing are more particularly worthy of notice. The the priest epopt, fays the code, " will take care that the writ- or epopt.

30 and blaf-

ty;

Illuminati. ings of the members of the order shall be cried up, and that the trumpet of fame shall be founded in their honour. He will also find means of hindering the reviewers from casting any suspicions on the writers of the fect." He is likewise instructed to bribe the common people into the interests of the order, and to corrupt their minds, by getting possession of schools and other seminaries of learning. But " if it be necessary for us to be masters of the ordinary schools (fays the impious legislator), of how much more importance will it be to gain over the Ecclesiastic seminaries and their superiors! With them we gain over the chief part of the country; we acquire the support of the greatest enemies to innovation; and the grand point of all is, that through the clergy we become masters of the middle and lower classes of the people."

Qualifications for the degree of regent.

to this de-

From the degree of epopt or priest are chosen the regents or prince-illuminees. On making this choice, fays the code, three things of the utmost consequence are to be observed. " 1/t, The greatest reserve is neceffary with respect to this degree: 2dly, Those who are admitted into it, must be as much as possible free men, and independent of princes: 3dly, They must have clearly manifested their hatred of the general constitution, or the actual state of mankind; and have shewn how evidently they wish for a change in the government of the world." If these requisites be found in an epopt who aspires to the degree of regent, six preliminary questions are put to him; of which the obvious meaning is to discover, whether he deems it lawful and proper to teach subjects to throw off the authority of their fovereigns, or, in other words, to destroy every king, minister, law, magistrate, and public authority on earth.

When these questions are answered to the satisfaction of his examiner, he is informed, "that as, in future, he is to be entrusted with papers belonging to the order of far greater importance than any which he has yet had in his possession, it is necessary that the order should have farther securities. He is, therefore, commanded to make his will, and infert a clause with respect to any private papers which he may leave, in case of sudden death. He is to get a formal or juridical receipt for that part of his will from his family, or from the public magistrate; and he is to take their promifes in writing, that they are to fulfil his intentions." This precaution being taken, and the day fixed for his inauguration, he is admitted into an antechamber hung with black, where he fees a skeleton, Admission elevated two steps, with a crown and fword lying at its feet. Having given up the written dispositions, &c. respecting his papers, his hands are loaded with chains as if he were a flave, and he is left to his meditations. A dialogue then takes place between his introducer and the provincial, who is feated on a throne in a faloon adjoining. It is in a voice loud enough to be Illumination heard by the candidate, and confilts of various queftions and answers; of which the following may serve for a specimen:

Prov. Who has reduced him to this state of sla-

Ans. by the Introd. Society, Governments, the Sciences, and false Religion.

Prov. And he wishes to cast off this yoke, to become a scditious man and a rcbel?

Anf. No; he wishes to unite with us, to join in OUR FIGHTS AGAINST THE CONSTITUTION OF GO-VERNMENTS, the corruption of morals, and the profanation of religion. He wishes, through our means, to become POWERFUL, that he may attain the GRAND UL-

Prov. Is he superior to prejudices? Does he prefer the general interest of the universe to that of more limited affociations?

Anf. Such have been his promifes.

Prov. Ask him, whether the skeleton which is before him be that of a king, a nobleman, or a beggar?

Ans. He cannot tell; all that he sees is, that this skeleton was a man like us; and the character of man is all that he attends to.

After a great deal of infidious mummery like this, the epopt is admitted to the degree of prince; but before his investiture with the infignia of that order, he is exhorted to be free, i. e. to be a man, and a man who knows how to govern himself; a man who knows his duty, and his imprescriptible rights; a man who ferves the universe alone; whose actions are folely directed to the general benefit of the world and of human nature. " Every thing else (fays the provincial) is INJUS-A long panegyric is then made on the happiness which will be experienced by mankind, when every father of a family shall be fovereign in his tranquil cot! when he that wishes to invade these facred rights shall not find an afylum on the face of the earth! when idleness shall be no longer suffered; and when the clod of useless sciences shall be cast aside (c)!

The fign of this degree confifted in extending out Sign of the the arms to a brother with the hands open; the gripe degree. was to feize the brother by the two elbows, as it were to prevent him from falling; and the word was RE-DEMPTION! The epopt was invested with his principality by receiving a buckler, boots, a cloak, and a hat; and on receiving the boots, he was defired to fear no road which might lead to the propagation or discovery of happiness. Thus decorated, the prince illuminee received the fraternal embrace, and heard the instructions for his new degree.

One would think that the adept had now arrived at

(c) This will naturally furprise our readers; but it could not surprise him to whom it was addressed; for when candidate for the priesthood, he had been asked, "Do the sciences which men cultivate furnish them with real lights? Are they conducive to real happiness? Are they not, on the contrary, the offspring of numberless wants, and of the unnatural state in which men live? Are they not the crude inventions of crazy brains?" There were, however, to be academies for the cultivation of fuch sciences as suited the designs of the order-Each academy was to confift of nine epopts, of whom seven were to preside respectively over so many departments of science, whilst the other two were to officiate as secretaries. One of the departments included the occult sciences, to which belonged the art of raising the seals of the letters of all who belonged not to the order, and of securing their own letters against similar practices!!

I minati. the very acmé of profanenels, and treasonable conspiracy. He has been initiated in mysteries which burlefque Christianity and its Divine Author, and at the fame time vow vengeance against all government, all law, and all science: yet Weishaupt, in a letter to Cato Zwack, his incomparable man, fays, that he has composed four degrees above that of regent, or prince-illuminee; with respect even to the lowest of which, his degree of priest will be found no more than child's play. "The ritual of these degrees, (says he), I never fuffer to go out of my hands. It is of too serious an import; it is the key of the antient and modern, the religious and political, history of the universe."

This caution of the chief conspirator has deprived us of the power to give fo particular an account of these degrees as we have done of the preceding; but the Abbé Barruel affures us that they were reduced to two, viz. that of Magus, and that of the Man-King; and that these two constituted the GREATER MYSTE-RIES. When the adept was admitted to the degree of magus, he was illuminized only in philosophy and religion; when to that of man-king, new lights were given him respecting property, and every species of political association. The Abbé quotes a passage from the Critical history of all the degrees of illuminism, written by a man of honour, who had paffed through them all, which will give the reader a fufficient idea of the object of these last degrees.

"With respect to the two degrees of magus and of degrees man-king (fays this writer), there is no reception, that is to fay, there are no ceremonies of initiation. Even the elect are not permitted to transcribe these degrees; they only hear them read, and that is the reason why I do not publish them with this work. The first is that of Magus, called also philosopher. It contains the fundamental principles of Spinozism. Here every thing is material; God and the world are but one and the fame thing: all religions are inconfishent, chimeri-

cal, and the invention of ambitious men."

37 jects of

That this is the doctrine of Spinoza, and that Spinoza was an atheist, is most certain; but though nothing can be effentially worse than atheism, we are strongly inclined to suspect that, at the initiation of the Magus, expressions must have been used more shocking at least to the ear than the philosophic jargon of the apostate Jew. It is long fince the philosophy of Spinoza was in Germany recommended from the press (see Spinoza, Eneyel.); it is but very lately that a professor in the university of Jena published a book, in which he teaches that there is no God, and that we abfurdly give that title to the relations of Nature (D); and fomething approaching fo near to atheim had been communicated to the adept when he was admitted to the priesthood, that we are persuaded Weishaupt must have alluded to language at least different from that in which Spinoza taught his dark doctrines, and that language, accompanied perhaps with impious and audacious gestures, when he faid that, compared with his higher mysteries, his degree of pricft was but child's play. What gives some degree of probability to this conjec-

ture, if it be nothing more, is the following fact related by Illumination the Abbé Barruel. During the French revolution (fays that able and well informed writer), a comedian appear- Atheism ed (E), dressed in the facerdotal robes of the illuminees, and and personally defying Almighty God. "No! (faid the impious wretch) thou dost not exist. If thou hast power over the thunderbolts, grafp them; aim them at the man who dares fet thee at defiance in the face of thy altars. But no! I blafpheme thee, and I still live. No! thou dost not exist." It will be seen by and byc, that the chiefs of the revolution, and even numbers of their tools, were illuminized; and is it improbable that this blasphemer, who was arrayed in the infignia of the epopts, made use of the language and gestures of the higher mysteries? Whether it be or not, M. Barruel has proved, even from the writing's of Weishaupt himfelf, that the magi were at least atheists of the school of

"The fecond degree of the grand mysteries, called the Man king, teaches (according to the author of the Critical History), that every inhabitant of the country or town, every father of a family, is fovereign, as men formerly were in the times of the patriarchal life, to which mankind is once more to be carried back; that in consequence all authority and all magistracy must be

destroyed."

This may appear to be nothing more than what the Savagifm. adept has been already taught in the leffer mysteries; and it is in fact nothing more than that to which he must have seen these mysteries tending; but the reader understands not the language of the illuminees, if he supposes that, by the patriarchal state, they mean such a ftate as that of the patriarchs of the Old Cestament. No! their patriarchal state is the fancied savage state of the atheiltical philosophers of Greece and Rome, when mankind had neither property nor fixed habitation. This is evident from one of the discourses of the hierophant; in which he tells the adept, that it would have been happy for man "had he known how to preferve himself in the primitive state in which Nature had placed him! But foon the unhappy germ developed itself in his heart, and rest and happiness disappeared. As families multiplied, the necessary means of sublistence began to fail. The Nomade or roaming life ceased; property began; men chose fixed habitations; agriculture brought them together; LIBERTY WAS RUINED IN ITS FOUNDATIONS, AND EQUALITY DISAPPEARED."

To restore that liberty and equality, therefore, which is the ultimate object of the order, and constitutes the MAN-KING, all property must be abolished, every house burnt, as well the cottage of the peafant as the palace of the prince; and mankind must once more inhabit woods and caverns without clothes and without fire, and fally out occasionally to encounter their fellowbrutes, and to fearch for food among the wild herbs of the defart. According to Mochus the Phenician, and the Greek philosophers of this hopeful school, this was the original state of man *; and to this state it was the * See object of Weishaupt and his adepts to reduce man again, . Dog's Let-Hence we hear them lavishing the most rapturous enco-ters on the

miums Savage

(D) We learned this from the letter already quoted in note (A.) (E) He does not fay where this appearance was made; but the circumstances related lead us to suppose that it was in a church.

Huminati miums on the Goths and Vandals who over-ran the second to the arts of secretly gratifying their passions. Illuminate Roman empire, annihilated the arts, put a stop to The wife of an adept named Ptolemy Magus was to agriculture, and burnt the towns and villages of civilized Europe! It was thus, according to the illuminees, that those barbarians regenerated mankind: but the regeneration was not complete; for the Goths and Van-dals could not preferve themselves from the contagion of civil life; and their fall from favagifm to science drew from Weisnaupt's hierophants the most piteous lamenta-

The last fe-

The last fecret communicated to the most favoured cret of the adepts was the novelty of the order. Hitherto their order. zeal had been inflamed, and their respect demanded to an inflicution pretended to be of the highest antiquity. The honour of inflituting the mysteries had been faccessively attributed to the children of the Patriarchs, to ancient philosophers, even to Christ himself, and to the founders of the majoric lodges (fee Masonay in this Suppl.). But now the time is come when the adept, initiated in the higher mysteries, is supposed to be sufficiently enthusiastic in his admiration of the order, to be entrufted with the history of its origin. Here then they inform him, that this fecret fociety, which has fo artfully led him from mystery to mystery; which has with fuch perfevering industry rooted from his heart every principle of religion, all love of his country, and affection for his family; all pretentions to property, to the exclusive right to riches, or to the fruits of the earth; -this fociety, which has taken fo much pains to demonstrate the tyranny and despotism of all laws human and divine, and of every government, whether monarchical, aristocratical, or republican; which has declared him free, and taught him that he has no lovereign on earth or in heaven; no rights to refrect in others, but those of perfect equality, of favage liberty, and of the most absolute independence; that this fociety is not the offspring of an ignorant and fuperilitious antiquity, but of modern philosophy; in one word, that the true father of illuminism is no other than Adam Wenhaupt, known in the fociety by the name of Sparacus! This important feeret, however, remained a myflery even to the greater part of the maci and the man-kings, being revealed only to the grand council of areopagites, and to a few other adopts of diftinguished merit.

Propofal order.

So zealoufly was the order bent upon propagating for a female its execuable principles through the whole would, that fome of the chiefs had planned an order of female adepts, in fubferviency to the defigns of the mon, " It will be of great fervice, (fays Cuto-Zwack). it will procure us both information and money, and will fuit charmingly the tafte of some of our truest members, who are lovers of the fex " An affelior of the Imperial chamber at Wetzlar, of the name of Dittfurt, but known among the illuminues by that of Alines, expreffed even his despair of ever bringing men to the grand object of the order without the support of female adepts; and he makes an offer of his own wife and his four daughters in law to be first initiated. This order was to be subdivided into two classes, each forming a separate society, and having different se-crets. The sirft was to be composed of virtuous women; the fecond of the wild, the giddy, and the voluptuous. The brethren were to conduct the first, by

prefide over one of the classes; which (lays Minos) will become, under her management and his, a very pretty fociety. "You must contrive pretty degrees, and dresses, and ornaments, and elegant and decent rituals. No man must be admitted. This will make them more keen, and they will go much faither than if we were prefent, or than if they thought that we knew of their proceedings. Leave them to the fcope of their own fancies, and they will foon invent mysteries which will put us to the bloth, and mysteries which we can never equal. They will be our great apostles. Reflect on the respect, nay, the awe and terror, inspired by the female myftics of antiquity. Ptolemy's wife must direct them, and she will be instructed by Ptolemy; and my stop-daughters will consult with me. We must always be at hand to prevent the introduction of any improper question. We must prepare themes for their difensaon: thus we shall confess them, and inspire them with our fentiments. No man, however, muit come near them. This will fire their roving fancies, and we may expect rare mysteries!"

But notwithstanding all the plans and zeal of this Rejeded prodigate wretch and others of the fraternity, it does by sparta. not appear that the General Spartacus ever confented cus. to the establishment of the fisterhood. He supplied, however, the want of fuch an institution, by secret inthrustions to the regents, on the means of making the influence of women over men subservient to the order, without entiulting them with any of the fecrets. "The fair fex (fays he) having the greatest part of the world at their disposal, no sludy is more worthy the adept than the art of flattery, in order to gain them. They are all more or less led by vanity, curiofity, pleasure, or the love of novelty. It is on that fide, therefore, they are to be attacked, and by that to be rendered subservient to the order" That Weishaupt's fagacity had not on this occasion forfaken him, is very evident; fince it has been proved that the German fair, who were the correspondents of the illuminees, welcomed the French invaders of their native country *. Nay, fo lately as * Dr Robilet winter, our correspondent in Saxony heard several son's Pross of these illuminized ladies express a wish that the of a Config. French might invade and conquer England; for then, Facy.

faid they, ica and coffee would be cheaper !

It is not enough for the founder of a fect of conspirators to have fixed the precise object of his plots. His accompliees must form but one body, animated by one spirit; its members must be moved by the same laws, under the inspection and government of the same chiefs. A full account of the government of Weishaupt's order will be found in the valuable work of Abbé Barruel; our limits permit us to give only fuch a general view of it as may put our readers on their guard against the fecret machinations of these execrable villains, whose lodges are now recruiting, under different denominations, in every country in Europe.

Wherever illuminism has gained a footing, as the means Subordinaof fuhordination, there is a general division of command tion of the as well as of locality. The candidates and novices are each illuminess. under the direction of his own infinuator, who introduces him into the Minerval lodges; each Minerval lodge has a superior from among the preparatory class, under the promoting the reading of good books; and to train the inspection of the intermediary class. So many lodges con-

Mu nati. flitute a district, under the direction of a superior, whom the order calls dean. The dean is subjected to the provincial, who has the inspection and command of all the lodges and deaneries of the province. Next in order comes the national superior, who has full power over all within his nation, provincials, deans, lodges, &c. Then comes the supreme council of the order, or the areopagites, over which prefides the general of illuminism. Thus has the order formed within itself a supreme tribunal, to whose inquisition all nations are to be subjected. The areopagites, confishing of twelve fathers of the order, with the general at their head, form the centre of communication with all the national fuperiors on earth; each notional is the centre of one particular nation; the provincial, of one province; the dean, of the lodges within his deanery; the minerval master, of his academy; the venerable, of his masonic lodge; and the insinuator or recruiter, of his novices and candidates.

The higher degrees (fays Weishaupt in one of his instructions to the regents) must always be hidden from the lower. The simple illuminee, therefore, corresponds with his immediate superior, knowing perhaps no other member of the order; the latter, with his dean; and thus gradually afcending to the national superiors, who alone are acquainted with the refidence of the areopagites, as they again are with the name and relidence of the general. Any member, however, of the inferior degrees, may occasionally correspond with his unknown superiors, by addressing his letters Quibus licet; and in these letters he may mention whatever he thinks conducive to the advancement of the order. If he be a novice, he may in these letters inform his superiors how his instructor behaves to him, or may draw the character of any person whatever. When the letter of any adept contains fecrets, or complaints which he chuses to conceal from his immediate superior, he directs it Soli or Primo; and then it can be opened only by the provincial, the national superior, the areopagites, or the general, according to the rank of the writer, which is by some contrivance unknown to M. Barruel, indicated on the outfide of the letter. The provincial opens the letters of the minor and major illuminees which are directed Soli; the Quibus licets of the epopts; and the Primos of the novices; but he cannot open either the Primo of the minerval, the Soli of the Scotch knight, or the Quibus licet of the regent. He can only form a conjecture as to the persons who open his own letters, and those which he is not permitted to open himself.

When it is confidered, that by one of Weishaupt's statutes, the provincial has in each chapter or district rtance to a confidential epopt, who is his secret censor or spy; ir order, that these spies are to infinuate themselves into all companies, and collect anecdotes of secret history; that the historian of the province is to infert these anecdotes into a journal kept for that purpose; and that the provincials are obliged to forward the contents of thefe journals to the high superiors of the order -- some notion may be formed of the influence of the general and areopagites in every country into which illuminism has found its way. "The means of acquiring an afcen-

dancy over men (says Weishaupt) are incalculable. Illuminati. Who could enumerate them all? They must vary with the disposition of the times. At one period, it is a tafte for the marvellous that is to be wrought upon. At another, the lure of fecret focieties is to be held out. For this reason, it is very proper to make your inferiors believe, without telling them the real state of the case, that all other secret societies, particularly that of Freemasonry, are secretly directed by us. Or else, and IT IS REALLY THE FACT IN SOME STATES, THAT PO-TENT MONARCHS ARE GOVERNED BY OUR ORDER. When any thing remarkable or important comes to pass, hint that it originated with our order. Should any person by his merit acquire a great reputation, let it be generally understood that he is one of us.

" If our order cannot establish itself in any particu-By every lar place, with all the forms and regular progress of good on our degrees, fome other form must be assumed. Always had have the object in view; that is the effectial point. No matter what the cloak be, provided you succeed; a cloak, however, is always necessary, for in secrecy our strength lies. The inferior lodges of free-MASONRY ARE THE MOST CONVENIENT CLOAKS for our GRAND OBJECT; because the world is already familiarised with the idea, that nothing of importance or worthy of their attention can spring from masonry." No artifice, however, is to be left untried. "You may attend large and commercial towns during the times of fairs in different characters; as a merchant, an officer, an abbé. Everywhere you will personate an extraordinary man, having important bufiness on your hands; but all this must be done with a great deal of art and caution, lest you should have the appearance of an adventurer. You may write your orders with a chymical preparation of ink, which disappears after a certain time. Never lose fight of the military schools, of the academies, printing presses, libraries, cathedral chapters, or any public establishments that can influence education or government. Let our regents perpetually attend to the various means, and form plans, for MAKING US MA-STERS of all these establishments. When an author sets forth principles true in themselves, but which do not as yet fuit our general plan of education for the world, or principles, the publication of which is premature; every effort must be made to gain over the author: but should all our attempts fail, and we should prove unable to entice him into the order, let him be discredited

by every possible means." Of their methods of discrediting authors, one has come to our knowledge, which must be interesting to some of our readers. Dr Robison's work, entitled Proofs of a Conspiracy, &c. which first unmasked these hypocrites in this country, found its way into Germany, and was translated into the German language, and exposed to sale at the Leipsic fairs. The illuminees, under the disguise of merchants and abbés, attended, and bought up the whole impression, which they committed to the flames. A fecond edition was published, and it shared the same fate (F). This was a more compendious way of answering the learned au-

(r) This information was communicated to us by a gentleman of character, who was at Leiplic when the two impressions of the book were thus disposed of. The Abbé Barruel's work has no doubt been answered in the same way, though we cannot say so upon the same authority.

of France

Illuminati thor than that which has been adopted by the Jacobin of Abbé Barruel and Dr Robison, to which we refer Illuminati journalists in London; but perhaps it may convince the readers of these journals, that the Doctor has not fo far mistaken the sense of the writings of Philo and Spartaeus, as their illuminised masters wish them to be-

When thefe arts of diffeminating the diforganizing and impious principles of the order are duly confidered, and when it is remembered that its emiffaries dare not disobey a fingle injunction of the high superiors, without exposing themselves to poilon, or to the daggers of a thouland unfeen affaffins, no man can be furprifed to learn that the illuminees contributed greatly to the 47 reach revolution. The philosophers of France had indeed prepared the public mind for embracing readily the doctrines of illuminism; and so early as 1782, Philo and Spartacus had formed the plan of illuminizing that nation; but they were afraid of the vivacity and caprice of the people, and extended not their attempts, at that time, beyond Strasbourg. Already, however, there existed some adepts in the very heart of the kingdom; and the Marquis de Mirabeau, when ambassador at the court of Berlin, was initiated at Brunfwick by a disciple of Philo Knigge's. On his return to France he began to introduce the new mysteries among his masonic brethren.

48 By means

The flate of free masonry was at that time peculiarly adapted to the views of the conspirators. The French had engrafted on the old and innocent British masonry of free ma- a number of degrees, gradually rifing above each other, to the very mysteries of illuminism itself (See Mason-RY, in this Suppl.). These were called the philosophical degrees, and comprehended the knights of the fun, the higher Rosicrucians, and the knights Kadesh. At the head of all these societies, whether antient or modern, were three lodges at Paris, remarkable for the authority which they exercised over the rest of the order, and Philip of Orleans was the grand-mafter. So early as the year 1787, France contained 282 towns, in which were to be found regular lodges, under the direction of that execrable wretch. He increased their number by introducing to the masonic mysteries the lowest of the rabble, as well as those French guards whom he destined to the subsequent attack of the bastile, and to the storming of the palace of his near relation and royal master. In every country town and village lodges were opened for affembling the workmen and peafantry, in hopes of heating their imaginations with the fophisticated ideas of equality and liberty, and the rights of man; and it was then that Mirabeau invited a deputation from the order of Weishaupt, which very quickly diffused the light of illuminism through the whole kingdom. Instead of Spartacus: Weishaupt, Cato-Zwack, and Philo-Knigge, we find wielding the firebrands of revolution in the capital of France, Philip of Orleans, Mirabeau, Syeyes, and Condorcet. 'I'he day of general infurrection was fixed by these miscreants for the 14th of July 1789. At the same hour, and in all parts of France, the cries of equality and liberty resounded from the lodges. The Jacobin clubs were formed; and hence fprung the revolution, with all its horrors of atheism, murder, and massacre!

our readers for much curious information that our limits do not permit us to give. We cannot, however, conclude the article, without making fome remarks on that specious principle by which the conspirators have deluded numbers, who abhor their impieties, and who would not go all their length even in rebellion; we mean the maxim, that " it is our duty to love all men with an equal degree of affection, and that any partial regard for our country, or our children, is unjust."

That this maxim is false, every Christian knows, be-Restedion cause he is enjoined to "do good indeed unto all men; on the funbut more effecially to them who are of the household of damental faith;" because he is told, that " if man any provide not principles for his own, and especially for those of his own house, mim; he hath denied the faith, and is worfe than an infidel;" because his divine master, immediately after resolving all duty into the love of God and man, delivers a parable, to flew that we neither can nor ought to love all men equally; and because the same Divine Person had one diseiple whom he loved more than the rest. But we wish those philosophers who talk perpetually of the mechanism of the human mind, and at the same time affect to have no partial fondness for any individual, but to love all with the same degree of rational affection, to confider well whether such philanthropy be confiftent with what they call (very improperly indeed) mechanism. If this mechanism be (as one of them says it is) nothing more than attraction and repulsion, we know that it cannot extend with equal force over the whole world; because the force of attraction and repulsion varies with the distance. If by this abfurd phrase, they mean a fet of inflinctive propenfities, or feelings, we know that among favages, who are more governed by instinct than civilized men, philanthropy is a feeling or propenfity of a very limited range. If they believe all our passions to originate in self love, then is it certain that our philanthropy must be progressive; embracing first, and with strongest ardour, our relations, our friends, and our neighbours; then extending gradually through the fociety to which we belong; then grasping our country; and last of all the whole human race. Perhaps they may fay that reason teaches us to love all men equally, because fuch equal love would contribute most to the sum of human happiness. This fome of them indeed have actually faid; but it is what no man of reflection can possibly believe. Would the fum of human happiness be increased, were a man to pay no greater attention to the education of his own children than to the education of the children of strangers? were he to do nothing more for his aged and helpless parents than for any other old person whatever? or, were he to neglect the poor in his neighbourhood, that he might relieve those at the distance of 1000 miles? These questions are too absurd to merit a ferious answer.

When a man, therefore, boafts of his universal benevolence, declaring himself ready, without fee or reward, to facrifiee every thing dear to him for the benefit of strangers whom he never faw; and when he condemns, in the cant phrase of faction, that narrow policy which does not confider the whole human race as . In support of this account of the illuminees we have one great family—we may fafely conclude him to be not loaded our margin with authorities; because our either a consummate hypocrite, who loves none but detail has been taken wholly from the valuable works himself, or a philosophical fanatic, who is at once a

The inati stranger to his duty and to the workings of his own Im fect

If this conclusion require any farther proof, we have it in the conduct of Weishaupt and his areopagites. Exellifi- In the hand writing of Cato, his incomparable man, was found the description of a strong box, which, if forced the unireceipts for procuring abortion; a composition which blinds or kills when spurted in the face; tea for procuring abortion; Herbæ quæ habent qualitatem delateream; a method for filling a bed-chamber with pestilential vapours; how to take off impressions of seals, so as to use them afterwards as feals; a receipt ad excitandum furorem uterinum; and a differtation on suicide. Would genuine philanthropists have occasion for such receipts as these? No! the order which used them was founded in the most confummate villany, and by the most detestable hypocrite. The incestuous Weishaupt seduced the widow of his brother, and folicited poison and the dagger to murder the woman whom he had fondly pressed in his arms. "Execrable hypocrite (says M. Barruel), he implored, he conjured both art and friendship, to deffroy the innocent victim, the child, whose birth must betray the morals of his father. The scandal from which he shrinks, is not that of his crime: it is the fcandal which, publishing the depravity of his heart, would deprive him of that authority by which, under the cloak of virtue, he plunged youth into vice and error. I am on the eve, (fays he) of losing that reputation which gave me fo great authority over our people: My fifter-in law is with child. I will hazard a desperate blow, for I neither can nor will lose my honour." Such is the benevolence of those who, banishing from their minds all partial affection for their children and their country, profess themselves to be members of one great family, the family of the world!

IMAGINARY QUANTITIES, or Impossible Quantities, in algebra, are the even roots of negative quantities; which expressions are Imaginary, or impossible, or opposed to real quantities; as $\sqrt{-aa}$, or $4\sqrt{-a^4}$, &c. For as every even power of any quantity whatever, whether positive or negative, is necessarily positive, or having the fign +, because + by +, or - by -, give equally +; hence it follows that every even power, as the square for instance, which is negative, or having the fign -, has no possible root; and therefore the even roots of fuch powers or quantities are faid to be impossible or imaginary. The mixt expressions arifing from imaginary quantities joined to real ones, are also imaginary; as $a - \sqrt{-aa}$, or $b + \sqrt{-aa}$.

IMAGINARY Roots of an equation, are those roots or values of the unknown quantity, which contain some imaginary quantity. Thus, the roots of the equation xx + aa = 0, are the two imaginary quantities $+\sqrt{-aa}$ and $-\sqrt{-aa}$, or $+a\sqrt{-1}$ and $-a\sqrt{-1}$.

IMPACT, the simple or single action of one body upon another to put it in motion. Point of impact is

the place or point where a body acts.

IMPERFECT NUMBER, is that whose aliquot parts, taken all together, do not make a fum that is equal to the number itself, but either exceed it, or fall short of it; being an abundant number in the sormer case, and a defective number in the latter. Thus, 12 is an abundant imperfect number, because the sum of all its aliquot parts, 1, 2, 3, 4, 6, makes 16, which exceeds

the number 12. And 10 is a defective imperfect number, Impost because its aliquot parts, 1, 2, 5, taken all together, Impulsion.

make only 8, which is less than the number 10 itself. IMPOST, in architecture, a capital or plinth, to a pillar, or pilaster, or pier, that supports an arch, &c.

IMPULSION, is the term employed in the lan-Doctrine of guage of mechanical philosophy, for expressing a sup-Impulsion. posed peculiar exertion of the powers of body, by which a moving body changes the motion of another body by hitting or striking it. The plainest case of this action is when a body in motion hits another body at rest, and puts it in motion by the stroke. The body thus put in motion is faid to be IMPELLED by the other; and this way of producing motion is called IM-PULSION, to distinguish it from PRESSION, THRUSTING, or PROTRUSION, by which we push a body from its place without striking it. The term has been gradually extended to every change of motion occasioned by the

collision of bodies. When speculative men began to collect into general History of classes, the observations made during the continual ex-it. ertions of our own personal powers on external bodies, in order to gain the purposes we had in view, it could not be long before they remarked, that as we, by the strength of our arm, can move a body, can stop or any how change its motion; so a body already in motion produces effects of the fame kind in another body, by hitting it. Such observations were almost as early and as interesting as the other; and the attention was very forcibly turned to the general facts which obtained in this way of producing motion; that is, to the expifcation of the general laws of impulsion. We do not find, however, in what remains of the physical science of the ancients, that they had proceeded far in this classification. While mechanics, or the science of machines, had acquired fome form, and had been the subject of successful mathematical discussion, we do not find that any thing similar had been done in the science of impulse. Yet the artillery of ancient times was very ingenious and powerful. But although Vegetius, and Ammianus Marcellinus, and Hero, describe the mechanism of these engines with great care, and frequently with mathematical skill, we see no attempts to ascertain with precision the force of the missile weapon, or to state the efficacy of the battering ram, by measures of the momentum, and comparison of it with the resistance opposed to it. The engineers were contented with very vague notions on these points.

Aristotle, in his 20th Mechanical Question, and Galen in some occasional observations, are the only aux thors of antiquity whom we recollect as treating tho force of impulse as a quantity susceptible of measure. Their observations are extremely vague and trivial, chiefly directed, however, to the discrimination of the

force of impulse from that of pressure.

In more modern times, great additions had already been made to the affiftance we had derived from the impulfive efficacy of bodies in motion. Water mills. and wind-mills had been invented, and had been applied to fuch a variety of purpofes, that the engineers were falt acquiring more diffinet notions of the force of impulse. Naval construction was changed in such a manner, that there hardly remained any thing of the ancient rigging. The oblique action of wind and water were now found even more effective than the direct; and ships

fixed the attention of the engineers and of the speculatist on the numberless modifications of the force of

But it foon appeared that this was a refined branch of knowledge, and required a more profound fludy than any other department of the science of motion. At the same time, it was equally clear, that it was also of superior importance. Mills worked by cattle, or by mens hands, were everywhere giving place to wind and water-mills; and a ship alone appeared to every intelligent mechanician to be the greatest effort of human invention, and most deserving his careful study. All these improvements in the arts of life derived their efficacy from the impulse of bodies. The laws of impulfion, therefore, became the objects of fludy to all who pretended to philosophical science. But this is a branch of fludy wholly new, and derives little affiftance from the mechanical science already acquired; for that was confined to the determination of the circumstances which regulated the equilibrium of forces, either in their combined action on bodies in free space, or by the intervention of machines. But in the production of motion by impulse, the equilibrium is not supposed to obtain; and therefore its rules will not folve the most important question, "What will be the precise motion?"

Galileo, to whom we are indebted for the first discoveries in the doctrine of free motions, was also the first who attempted to bring impulsion within the pale of mathematical discussion. This he attempted, by endeavouring to state what is the force or energy of a body in motion. The very obscure reflections of A. ristotle on this subject only served to make the study more intricate and abstruse. Galileo's reslections on it are void of that luminous perspicuity which is seen in all his other writings, and do not appear to have fatiefied his own mind. He has recourse to an experiment, in order to discover what pressure was excited by impulsion. A weight was made to fall on the scale of a balance, the other arm of which was loaded with a confiderable weight; and the force of the blow was estimated by the weight which the blow could thus flart from the ground. The refults had a certain regularity, by which some analogy was observed between the weights thus flarted and the velocity of the impulse; but the anomalies were great, and the analogy was fingular and puzzling; it led to many intricate discussions,

and science advanced but slowly.

At last the three eminent mathematicians, Dr Wallis, Sir Christopher Wrenn, and Huyghens, about the fame time, and unknown to each another, discovered by Wallis, the simple and beautiful laws of collision, and commu-Huyghens. nicated them to the Royal Society of London in 1668 (Phil. Trans. nº 43-46.). Sir Christopher Wrenn also invented a beautiful method of demonstrating the doctrine by experiment. The bodies which were made to strike each other were suspended by threads of equal length, fo as to touch each other when at rest. When removed from this their vertical fituation, and then let go, they struck when arrived at the lowest points of their respective circles, and their velocities were proportional to the chords of the arches through which they had descended. Their velocities, after the stroke, were measured, in like manner, by the chords of their arches

Impulsion could now fail with almost any wind. All these things of ascent. "The experiments corresponded precisely impulsion with the theoretical doctrine.

In the mean time, this subject had keenly occupied the attention of philosophers, who found it to be of a very abstruse nature; or, which is nearer the truth, they indulged in great refinement in profecuting the study. The first attempts to measure the impulsive force of bodies, by fetting it in opposition to pressures, which had long been measured by weights, gave rise to some very refined reflexions on the nature of these two kinds of forces. Aristotle had faid that they were things altogether disparate. If so, there can be no proportion between them. Yet the analogy observed in the experiments above mentioned of Galileo, shewed that impulse could be gradually augmented, till it exceed any pressure. This indicates sameness in kind, according to Euclid himself. A curious experiment of Galileo's, in h the impulse of a vein of water was fet in equilibrio with a weight, feemed not only to establish this identity beyond a doubt, but even to shew the origin of pressure itself. The weight in one scale is fustained as long as the stream of water continues to firike the other scale. In this experiment, therefore, pressure is equivalent to continual impulse. But continual impulse is not conceivable: we must consider the impulse of the stream as the successive impulse of the different particles of water, at intervals which are altogether indistinguishable.

From these considerations were deduced two very momentous doctrines: 1. That pressure is nothing but repeated impulse; 2. That although pressure and impulse are the same in kind, they are incomparable in magnitude. The impulse is equal to the weight of a column of water, whose length is the height necesfary for communicating the velocity. Now this is incessant; and the weight is sustained during any the smallest moment of time, by the impulse, not of the whole column, but of the infensible portion of it which is then making its stroke. Impulse, therefore, is infi-

nitely greater than pressure.

These abstruce speculations have a charm for certain Impulse ingenious foeculative minds; and when indulged, will faid to be lead them very far. Accordingly, it was not long before the only fome of the most ingenious philosophers of Europe cause of taught that impulse was the sole origin of pressure. motion. There is but one moving power (faid they) in mechanical nature: This is impulse. - Nihil movetur (fays Euler) nisi a contiguo et moto. Moreover, having been long and familiarly converfant with the actions of animals, and the actions of moving bodies, and conceiving, with sufficient distinctness, that impenetrable bodies cannot move without moving those with which they are furrounded and in contact, they imagined that they fully understood how all this displacement of bodies is carried on; and therefore they maintained, that any motion is fully explained when it is shewn to be a case of impulsion. But they saw many cases of motion where this impulsion could not be exhibited to the senses. Thus, the fall of heavy bodies, the mutual approach or recess of magnetic and electric bodies, exhibited no fuch operation. But even here their experience helped them to an explanation. Air is an invisible substance, and its very existence was for a long time known to us only by means of its impulse. As we see that pressures are

Laws of impulfion discovered Dallion generated by the impulse of water and of air, may there not be fluids still more subtle than air, by whose invifible impulse bodies are made to fall, and magnets are made to approach or avoid each other? The imposfibility of this cannot be demonstrated, and the laws of impulse had not as yet been so far investigated as to flew that they were incompatible with those productions of motion. It was therefore an open field for dif cuffion; and the philosophers, without farther hesitation, adopted, as a first truth, that ALL MOTION WHAT-EVER IS PRODUCED BY IMPULSION. The bufiness of the philosopher, therefore (fay they), is to investigate what combination of invisible impulsions is competent to the production of any observed motion; such as the fall of a heavy body, the elliptical motion of a planet, or the polarity of a magnetic needle. The curious dispofition of iron-filings round a magnet encouraged this kind of speculation: It looks so like a stream of fluid; but it is a number of quiescent fragments of iron. This does not hinder us from fuppoling fuch a stream, not of iron-filings, but of a magnetic fluid, which will arrange (fay the atomists) those fragments, just as we see the flote grass in a brook arranged by a stream of water. Fluids, therefore, moving in streams, vortices, and a thousand different ways, have been supposed, in order to explain, that is, to bring under a general known law of mechanical Nature, all those cases of the production of motion where impulsion is not observed by the fenses.

As we have gradually become better acquainted with the laws of the production of motion by impulsion, we have been able to explode many of those proffered explanations, by shewing that the genuine results of the supposed invisible motions, that is, the impulsions which they would produce, are very unlike the motions which we attempt to explain. It has been shewn, that the vortices supposed by Des Cartes, or by Leibnitz, or by Huyghens, cannot exist; and they have been given up. But, it is answered to all those demonstrations of futility, that full the axiom remains. Motion is produced only by impulse; but we have not yet discovered all the possibilities of impulsion; and we must not despair of discovering that precise set of invisible motions, and confequent impulsions, of which the phenomenon before us is the necessary result. But this is by no means sufficient authority for de

he appliferting the rule of philosophizing, so prudently and ju diciously recommended by Sir Isaac Newton; namely, ple is ha- not to admit as the cause of a phenomenon any thing that is not feen to operate in its production. The prudence of this restriction is evident; and it has also been fufficiently shewn (Philosophy, Encycl. nº 48. &c.), that true philosophical explanation, or extension of knowledge, is unattainable, if this rule be not strictly adhered to. We therefore require a cogent reason for a practice that opens the door to every abfurdity, and that cannot give us the knowledge which we are in quest of. What, then, is the reason that always induces philosophers to have recourse to impulsion for the explanation of a phenomenon, and to rest satisfied in every

case where it can be clearly proved that the phenomenon is really a case of impulsion? We say that we inquire into the reason why a body falls, and that we will be fatisfied if it can be shewn us that it has received a number of impulsions downward. Do we inquire why

SUPPL. VOL. 1. Part II.

tion of

ardous.

a body in motion puts another body in motion by hit-Impulsion. ting it? And if we do, have we discovered the reason? We believe that none of the philosophers, who have recourse to invitible impelling fluids, ever ask a reason for motion by impulsion. Indeed they should not, otherwife it would cease to be a first principle of explanation. Other philosophers, indeed (namely, such as ask no reafon for the weight of a body, but the FIAT of the AL-MIGHTY), require an explanation of motion by impulse, and think that, in almost every case, they have found it out.

If the philosophers ask no reason for this production of motion, they must (that it may serve as a principle of explanation) fay that impulfiveness is an original property of matter, either contingent or effential. Accordingly, we believe that this, or fomething like this, has been affumed as a principle by the greater part of mechanicians. It has been affirmed, as we have observed in the article DYNAMICS, Suppl. that a moving body possesses the power of producing motion in another body by hitting it; and they call it the IMPULSIVE FORCE of moving bodies - the FORCE INHERENT in a moving body. The reader will have observed, in our manner of treating that article, and also in several passages of different articles of the Encyclopedia Britannica, that we do not confider this assumption as very clearly authorifed by observation, or deducible by abstract reasoning, from the first principles of philosophy. There is no branch of natural philosophy on which so many ingenious differtations have been written; and perhaps there is none that has been more successfully prosecuted: Yet this is the only part of the science of motion that has given rife to a serious dispute; a dispute that has divided, and still divides, the mechanicians of Europe.

Some may think it prefumptuous in us, in a Work of this kind, which only aims at collecting and exhibiting in one view the existing science of Europe, to pretend to give new doctrines, or to decide a question which has called forth all the powers of a Leibnitz, a Bernoulli, a Jurin, a M'Laurin, &c. But we make no fucl pretentions; we only hope that, by feparating the question from others with which it has, in every instance, been complicated, and by considering it apart, fuch notions may be formed, in perfect conformity to the principles adopted by all parties, that the mystery, which has gradually gathered like a cloud, may be difpelled, and all cause of difference taken away. We apprehend that this requires no very extensive knowledge, but merely a strict attention to the conceptions which we form of the actions of bodies on each other, and a precision in the use of the terms employed in the discuffion.

We trust that our philosophical readers perceive inquiry inand approve of our anxiety to establish (in the article to its truth. DYNAMICS, Suppl.) the leading principles of mechanical philosophy, from which we are to reason in future on acknowledged FACTS, or LAWS of human thought. It is not so much the question, What is the essence of material Nature, from which all the appearances in the universe proceed? as it is, What do we know of it? how do we come by this knowledge? and what use can we make of it? The tænia knows nothing of the solar fystem, and man is ignorant of the cause of impulsiveness. Other intelligent creatures may have fenses, of which this is the proper object; and others, of a still

Impulsion. more exalted rank, may perceive the operations of mind as clearly as we perceive those of matter, while they are equally ignorant with ourfelves of the causes which connect the conjoined events in either of those opera-But "known unto God, and to Him alone, are ALL His works !"

We learn the exist ence of matter chiefly by means of wouch.

To accomplish this purpose, we directed the reader's attention to what paffes in his own mind when he thinks on the mechanical phenomena of Nature; on what he calls body; on the perceptions which bring it into his view, and which give him all the notions that he can form of its diffinguishing, its characteristic properties. How does he learn that there is matter in a particular place? He has more than one mean of information; and each of these informs him of peculiar qualities of the thing which he calls matter. Many appearances fuggest to his mind the presence of a body. Show a monkey or a kitten (and even fometimes a human infant) a mirror, and it will instantly grope round it to find a companion. Why does the creature grope about fo? It is not contented with the first indication of matter, and nothing will fatisfy it but touching or grasping what is behind the mirror. It is by our sense of touch alone that we get the irrefistible conviction that matter or body is perceived by us, and it never fails to give us the perception; nay, we have the perception even in some cases where the experienced philosopher thinks himself obliged to doubt of its truth. Some fensations, arising from spasm, cannot be distinguished from the feeling of touch; and the patient infifts that fomething preffes on the difeafed part, while the physician knows that it is only a nervous affection. Every person will think that a cobweb touches his face when an electrified body is brought near it, and will try to wipe it off with his hand. But the modern philosopher sees good reason for afferting, that in this instance our feeling gives us very inaccurate, if not erroneous, information. He shews, that the fact, of which our feeling truly informs us, is the bending of the small hairs or down which grow on the face, and that thefe only have been touched; and the followers of Æpinus deny that even this has been demonstrated.

The excite-

The philosopher adopts this mode of perception as unquestionable, and allows that, and that alone, to be touch is ac matter, which invariably produces this fenfation by concompanied tiguity. But engaged in speculations which fix his attention on the external object, he neglects and overeried pref. looks the inftrument of information, and its manner of producing the effect, just as the astronomer overlooks the telescope, and the union and decussation of the rays of light which form the picture by which he perceives the satellite of Jupiter travel across his disk. The philosopher finds it convenient to generalife the immense variety of touches which he feels from external bodies, and to confider them as the operations of one and the same discriminating quality, a PROPERTY inherent in the external substance BODY; and he gives it a name, by which he can excite the fame notion in the minds of his hearers. It is worth while to attend to what has been done in this matter, because it gives much information concerning the first principles of mechanism. An exquisite painting has sometimes such an appearance of prominence, that one is disposed to draw the finger along it, and we expect to feel some roughness, some obstruction, something that prevents the fin-

ger from going over the place. Perhaps we doubt, and Impulsion. want to be affured. We press a little closer; but feel no obstruction; and we defift. The very first appearance, therefore, which this indicating quality, viewed as the property of external matter, has in our conceptions, is that of an obstruction, an obstacle, to the exertion of one of our natural powers. The power exerted on this occasion is familiarly and distinctively known by the name of PRESSURE. This is the name of our own exertion, our own action; and, in this instance, and (we think) in this alone, the word is used purely, primitively, and without figure. When we fay that a stone presses on the ground, we speak figuratively, as truly as when we say that the candlestick stands, and the snuffers lie, on the table. It is a personification, authority rifed by the fimilarity of the effects and appearances. Further, when we fpeak of our pressure on any thing, with the intention of being precise in our communication, we speak only of what obtains in the touching parts of the finger and the thing pressed, paying no attention to the long train of intermediate exertions of the mind on the nerves, the nerves on the mufcular fibre, the fibre on the articulated machine, and the machine on the touching part of the finger. And thus the exertion of the fentient and active being is attributed to the particles of lifeless inactive matter at the extremity of the finger, and these are said to press immediately on the touching parts of the external body. And, lastly, as this our exertion is unquestionably the perceived employment of a faculty in us, which we call force, power, frength, distinguishing it from every other faculty by these names; we say (but figuratively), that force or power is exerted at the tips of the fingers, and we call it the FORCE OF PRESSURE.

By far the greatest part of our actions on external and prefbodies is with the intention of putting them out of fure is contheir present situations; and we can hardly separate ceived or the thought of exerted preffure from the thought of supposed in motion produced by it. Therefore, almost at its first every proappearance in the mind, pressure comes before us as a duction of MOVING POWER. Nay, we apprehend, that the more motion. we speculate, and the more we aim at precision in our conceptions, we shall be the more ready to grant that we have no clear conception of any other moving power. No man will contend that he has any conception at all of the power exerted by the mind in moving the body. It is of importance to reflect on the manner in which this notion is extended to all other productions of motion. We think that this will shew, that in every case we suppose pressure to be exerted.

The philosopher proceeds in his speculations, and graninaobserves, that one man can press on another, and can teon of the push him out of his place, in the same way as he re instances of moves any other body; and he cannot observe any dif-this percepference in his own exertions and fentations in the two But the man who is pushed has the same feelings of touch and preffure. By withdrawing from the pressure, he also withdraws from the sensation; by withstanding or refissing it, he teels the pressure of the other man; and what he feels is the fame with what he feels when he preffes on the other person, or on any piece of matter. The fame fensations of touch are excited. He attributes them to the pressure of the o. ther person. Therefore he attributes the same lensations to the counter preffure of any other body that

that he is not pushed from his place. In this case, the by lifeless matter, similar trains of intervening operapullion, excites them. greatest pressure is exerted, and is felt by both. Each tions. In the case of a spring, we have discovered feels that the more he relists, the greater is the mutual that there is a certain combination of the properties of pressure. And each feels that, unless he not only do all its parts necessary for the visible exertion. But what not resist, but also withdraw himself from the pressure of is the principle which thus makes them co-operate, we the other, he will be pressed, and the other will feel cannot tell, any more than in our own exertions of counter-pressure, the same in kind with what is produced by his refistance, though less in degree.

IO cy are erally grative.

but they require attention, in order to be subjects of recollection and after confideration. From this, and no other fource, are derived all our notions of corporeal pressure, of counter-pressure, of action, re-action, of refissance, and of inactivity or inertia. Our notions of moving power, of the mobility of matter, and of the another body by hitting it, and endeavour to form necessity of this power to produce motion in matter, a notion of the way in which this motion is immehave the fame origin. Our notions also of the refift- diately produced, fixing our attention on what passes ance of inanimate matter, indicated by the expendi- in the very instant of the change, we find ourselves still by the same pressure that would displace a lifeless body of the same bulk.

II rve many effures.

These direct inferences are confirmed as we extend our acquaintance with things around us. We can exert our force in bending a spring, and we feel its counter-pressure, precisely similar to that of another man. We feel that we must continue this pressure, in order to keep it bent; and that as we withdraw our preffure, the fpring follows our hand, still producing similar feelings in our organs of touch, and requiring fimilar exertions of our strength to keep it in any state of ten fion. These phenomena are interpreted as indications of preffures actually exerted by the spring, and quite different from what we should feel from its mere refistance to being moved. This action refembles our own exertion in every particular; it produces all the effects of pressure; it will squeeze in the loft slexible parts of our body with which we act on it; it will compress any foft body, just as we do ourselves; it will put bodies in motion. Farther, we can set the action of one spring in opposition to that of another, and observe that each is bent by bending the other; and we fee that their touching parts exert preffure, for they will pullion is the only power in nature, and the fource of compress any foft body placed between them.

Thus, then, in all those cases, we have the same notion of the power immediately exerted between the two bodies, animated or inanimated. It is always preffure. If indeed we begin to speculate about the modus operandi in any one of these instances, we find that we must stop short. How our preffure excites the feeling of pressure in the other person, or how it produces motion, eludes even conjecture - So it is - Nay, how our intention and volition causes our limb to exert this preffure, or how the springiness of a spring produces similar effects, remains equally hid from our ken. Unwearied study has greatly advanced our knowledge of these subjects in one respect. It has pointed out to frame before the oftenfible pressure is produced: we have discovered something of their kind, and of the order in which they proceed; we have gone farther,

Farther, he can resist to such a degree, and have discovered, in some of the pressures exerted Impulsion. pressure. Such being the origin of our notions on these subjects, it is no wonder that all our language is All these things are distinctly and invariably felt; also derived from it. Force, power, pressure, action, re-action, refistance, impulsion, are, without any exception, words immediately expressive of our own exertions, and applied metaphorically to the phenomena of matter and motion.

Lastly, when we see a body in motion displace ture of actual pressure, are formed from the same pre- obliged to suppose the thing we call pressure. We can mifes: the counter preffure, or what at least produces have no other conception of it; and there is no violence the same feelings in the person who is the mover, is in this act of the imagination. For we know, that if we considered as the property of dead matter; because we are jostled from our place, and forcibly driven against anfeel, that if we do not exert real force, we are displaced other person, we put that person in motion without any intention or action of our own; and we experience, in doing this, that the very fame feelings of touch and preffure are excited as in the inftances of the fame motions produced by exerted preffion. We also see, that when a body strikes another, and puts it in motion, it makes an impreffion or dimple in it if foft, or breaks it if brittle; and in fhort, produces every effect of pressure. A ball of soft clay makes a dimple in the ball of foft clay which it displaces, and is dimpled by it. Springy bodies compress each other in their collisions, and resile from each other. In short, in every case of this class, mutual pressure, indicated by all its ordinary effects, appears to be the intermedium by which the changes of motion are immediately produced; and the previous motion of the striking body seems to be only the method of producing this pressure.

From this copious induction of particulars, and Pressure is careful attention to the circumstances of each, we think the only distinct noit plain, that preffure is the only clear notion that a distinct nomind, not familiar with ferupulous discussion, forms of moving moving power; and therefore that it is very fingular to power. think of excluding it from the lift, and faying that im-

It may perhaps be faid, that the mutual immediate action to which the vulgar, and many philosophers, have erroneously given the metaphorical name pressure, is, indeed, the real cause of motion or change of motion; but still it is now properly called impulsion, because it is occasioned only by the previous motion of the impelling body. We conceive clearly, (they may fay, how this previous motion produces the impulsion. Since matter is impenetrable, we see clearly that a solid body, or a folid particle, cannot proceed without displacing the bodies with which it comes into contact; we have notions of this as clear as those of geometry; whereas, how preffure is produced, is inconceivable by us a train of operations, which go on in our animal us. If we press a ball ever so strongly against another, will not move an inch, unless we continue to follow it, and press it forward; but we see a moving body pro-

5 G 2

duce

Impulsion duce compression, bend springs, make pits in soft bodies, and produce all the effects of real animal pressure. Impulse, therefore, is the true cause of motion, and the folicitation of gravity is nothing but the repeated impulse of an invisible fluid.

But, in the first place, let it be observed, that both parties profess to explain the phenomena of mechanical nature, that is, to make them easier conceived by the mind. Now it may be granted, that could we have any previous conviction of a fluid continually flowing toward the centre of the earth, we could have fome notion of the production of a downward motion of bodies, but not more explanation than we have without it, because impulsiveness is as little understood by us as pressure.

Many pref-

But there are thousands of instances of moving forces where we cannot conceive how they can be proinexplicable duced by the impulse of a body already in motion. by impul- There appear to be many moving powers in nature, independent of, and inexplicable by, any previous motion; these may be brought into action, or occasions may be afforded for their action, in a variety of ways. The mere will of an animal brings fome of them into action in the internal procedure of muscular motion: mere vicinity brings into action powers which are almost irrefistible, and which produce most violent motions. Thus a little aquafortis poured on powdered chalk contained in a bombshell, will burst it, throwing the fragments to a great distance. A spark of fire brings them into action in a mass of gunpowder, or other combustibles. And here it deferves remark, that the greater the mass is to which the spark is applied, the more violent is the motion produced. It would be just the contrary, if the motion were produced by impulse. For in all cases of impulsion, the velocity is inversely proportional to the matter that is moved. When a fpring is bent, and the two ends are kept together by a thread, a pressure is excited, which continues to act as long as the thread remains entire. What contrivance of impelling fluid will explain this, or give us any conception of the total ceffation of this prefiure, when the thread is broken, and the fpring regains its quiescent form?

14 All preffures do not produce a fenfible motion.

We can explain, in a most intelligible manner, why the hardest pressure produces no sensible motion in the case referred to above. We can conceive, with sufficient distinctness, a tube filled with steel wires, coiled up like cork ferews, and compressed together into toth of their natural length. A tube of 10 inches long will contain 100 of them. While in this state, compressed by a plug, we can suppose each of the springs to be tied with a thread. Suppose now that the thread of the fpring next the piston is burnt or cut; it will press on the pilton, and force it out, accelerating its motion till it has advanced one inch; after this, the piston will proceed with a uniform motion. It is plain, that the velocity will be moderate, perhaps hardly fensible, because the pressure acted on it during a very short time. But if two springs have been set at liberty at the same instant, the pressure on the piston will be continued through a space of two inches, and the final velocity will be greater, because the same (not a double) preffure will be exerted through a double space. Unbending four fprings at once, will give the pifton a double velocity (See DYNAMICS, Suppl. n°95). Now the effect of the anotion of the second spring is to keep the pressure of the

first in action during a longer time, by following it, and Impulsions keeping it in a state of compression. There is nothing fupposed of this kind in the case of strong pressure alluded to; and therefore no motion is produced when the obstacle is removed, except what the insensible compreifion produces by accelerating the body along an infenfible space. If all the 100 springs are disengaged at once, the pifton will be accelerated through 100 inches, and will acquire ten times the velocity that one spring can communicate. (N.B. The force expended in moving the fprings themselves is not considered here).

It is in this way only that the previous motion of the impelling body acts in producing a confiderable motion. The whole process will be minutely confi-

dered by and bye.

We may now ask, how it is so clear a point, that a Impulsion is folid body in motion must displace other bodies? This not more feems to be the very point in question, Is the affirma clearly contive deduced from our notion of folidity? What is our ceived than notion of folidity, and whence is it derived? We appre-preffure. hend that even this primary notion is derived from preffure. It is by handling a thing, and finding that we cannot put our hand into the place where it is without displacing it, that we know that it is material. All this is indicated to us by the feeling excited by our pressure. We feel this property always as an obstacle; and therefore fay, that by this property it refifts our pressure. Nay, there are cases where even the philofopher prefers this quality to impultiveness as a test of matter. To convince another that the jar out of which he has poured the water that filled it is not empty, but full of matter, he dips the mouth of the jar into water, and shows, that although he press it down till the surrounding water is above the bottom of it, the water has hardly gotten half an inch into the jar; there is fomething there which keeps it out; there is matter in it. He then opens a hole in the bottom of the jar; the water immediately rifes on the infide of the jar, and fills it. He fays that the pressure of the water has driven the matter out by the hole; and he confirms the materiality of what is expelled by holding a feather above the hole. It is agitated, shewing that the expelled thing has impulfiveness, another property (he fays) of matter: what filled the jar was air, and air in motion is wind. The philosopher can exhibit some new cases, where something like impulsiveness appears. A slender magnet may be set on one end, the fourh pole, for inflance, and will fland in that tottering fiture tion. If a person bring the north pole of a powerful magnet hastily near the upper end, it will be thrown down, just as it may be blown down by a puff of wind; therefore (fays the philosopher) there may be appearances of impulsion, and I may imagine that there is impelling matter; but nothing but matter excludes all other matter from its place: this property, therefore, is the furest test of its presence.

Thus we fee, that our notion of folidity or impenetrability (a name still indicating an obstacle to preffure), gives us no clearer conception of the productions of motion by impulsion than pressure does; for Motion it is the same, or indicated by the same sensations.

The question now feems to be reduced to this - Since impelby the strongest pressure of a quiescent body does not pro-transfusing duce motion, or excite that kind of preffure which is inherent the immediate cause of motion while a half is force or inthe immediate cause of motion, while a body in mo-herent moin illion. tion, exciting but a very moderate pressure (as may be feen by the triffing compression or dimpling), produces a very confiderable motion, how is the previous motion conducive to this purpose? The answer usually given is this: A body in motion (by whatever cause), perseveres in that motion by the inherent force; when it arrives at another body, it cannot proceed without displacing that body. The nature of the inherent force is such, that none of it is loft, and that a portion of it passes into the other body, and the two bodies instantly proceed with the same quantity of motion that was in the impelling body alone. This is an exact enough narrative of the general fact, but it gives no great explanation of it. If the impelling body perfeveres in its motion by means of its inherent force, that force is exerted in performing its office, and can do no more. The impelled body feems as much to possess an inherent force; for the same marks and evidences of pressure on both sides are observed in the collision. If both bodies are foft or compressible, both are dimpled or compressed. We are as much entitled, therefore, to fay, that part of the force by which it perseveres at rest, passes into the other body. But the rest, or quiefcence of a body, is always the fame; yet what paffes into the impelling body is different, according to its previous velocity. We can form no conception how the half of the inherent force of the impelling body is expended by every particle, paffes through the points of contact, and is distributed among the particles of the impelled body; nay, we cannot conceive this halving, or any other partition of the force. Is it a thing fui generis, made up of its parts, which can be detached from each other, as the particles of falt may be, and really are, when a quantity of fresh water is put into contact with a quantity of brine? We have no clear conception of this; and therefore this is no elucidation of the matter, although it may be an exact statement of the vihble fact.

Let us take the simplest possible case, and suppose only two particles of matter, one of which is at rest, and the other moves up to it at the rate of two feet per fecond. The event is supposed to be as follows: in the instant of contact, the two particles proceed with half of the former velocity. Now this inflant of time, and this precise point of space, in which the contact is made, is not a part of either the time or space before collision, or of those after collision; it is the boundary between both; it is the last instant of the former time, and the first instant of the latter time; it belongs to both, and may be faid to be in both. What is the state or condition of the impelling particle in this inflant? In virtue of the previous motion, it has the determination, or the force, or the power, to move at the rate of two feet per second; but, in virtue of the motion after collifion, it has the determination or power of moving at the rate of one foot per fecond. In one and the fame inflant, therefore, it has two determinations, or only one of them, or neither of them. And it may, in like manner, be faid of the impelled body, that, in that inftant, it was both at rest, and moving at the rate of one foot per fecond. This feems inconceivable or ab-

is in

ves ab-

It is not perhaps very clear and demonstrable, nor ess is not is it intuitively certain, that the moving body or parintuitive ticle must displace the other at all. All that we know operty of is, that matter is moveable, and that causes of this atter,

motion exist in nature. When they have produced Impulsion. this motion, they have performed their task, and the motion is their complete effect: the particle continues in this condition for ever, unless it be changed by some cause; but we do not see any thing in this condition. that enables us to fay what causes are competent to this change, and what are not. Is it either intuitive or demonstrable, that the mere existence of another particle is not a sufficient or adequate cause? Is it certain that the arrival at another particle is an adequate cause? or can we prove that this will not stop it altogether? The only conclusion that we can draw with any confidence is, that "two particles, or two equal bodies, meeting with equal velocities, in opposite directions, will stop. But our only reason for this conclusion is, that we cannot affign an adequate reason why either should prevail. But this form of argument never carries luminous conviction, nor does it even give a decision at all, unless a number of cases can be specified which include every possible refult. This can hardly be affirmed in the We apprehend that the next case, in point of sim. But an obpresent case.

plicity, has still less intuitive or deductive evidence; served facts namely, when bodies meet in opposite directions with equal quantities of motion. It is by no means eafy, if it be at all possible, to shew that they must stop. The proof proceeds on fome notion of the manner in which the impulsion, exerted on one particle, or on a few of each body, namely, those which come into contact, is distributed among all the particles. A material atom is moved only when a moving force acts on it, and each atom gets a motion precifely commensurate to the force which actuates it. Now, it is so far from beingclear, how a force impressed on one particle of a solid body occasions an equal portion of itself to pass into every particle of that body, and impel it forward in the fame direction, that the very authors who assume the prefent proposition as an elementary truth, claim no small honour for having determined with precision the moving forces that are exerted on each particle, and the circumstances that are necessary for producing an equal progressive motion in each. It was by no means an eafy problem to shew, that the motion of the body (estimated by an average taken of the motions of every particle) is precifely that which is announced by this proposition. We must also consider how this investigation is conducted. It is by affuming, that whatever force connects a particle a with a particle b, or whatever force a exerts on b, the particle b exerts an equal force on a in the opposite direction-Surely no logician will fay that this is an intuitive truth. The contrary is most distinctly conceivable. It was a discovery of the astronomers, that every deflection toward the fun is accompanied by an equal deflection of the fun. It was a discovery, that a piece of iron attracts a loadstone; and it was a discovery (and we dare not yet affirm it to be without exception), that every action of bodies is accompanied by an equal and contrary re-action. But this is by no means a first principle. It is the expression of a most generally observed fact, a sum to-tal of knowledge. When received on this authority, it is fully competent to folve every case of impulsion, independent of all obscure and illogical doctrines of force inherent in moving bodies, of force of inertia, of communication of motion, &c.

The impossibility of conceiving the detachment of

part

Impulsion, part of the force inherent in A, and transferring this part into B, and the fimilar impossibility of conceiving the imparting to B some of the motion that was in A, should make us reject any proposition involving such conceptions, and refuse its admission as an elementary truth. Much more should we reject a proposition that obliges us to suppose that a particle of matter has two determinations, forces, motions, or call them by any other name, in one and the same instant. One of these necessarily excludes the other. Indeed this was so evident, even to the most eminent partizans of the doctrine of the transfusion of inherent force, and others confequent on it, that they found themselves obliged to deny that there was fuch a thing in the world as a perfectly hard body, in which the motion must be instantaneously changed into another, differing from it by any fensible quantity. The existence of perfectly hard bodies is positively denied by the celebrated mathematician of Bafle, John Bernoulli, in his Differtation on the Communication of Motion, which contended for the prize given by the Academy of Sciences at Paris 1710. His reason for this rejection is singular. and fomewhat amusing. "In the collision of perfectly hard bodies, the conservatio virium vivarum, demonstrated by the most eminent mathematician (Mr Leibnitz), to be a law of nature, would be broken without any effect being produced. He does not observe, that it is as completely broken by elastic bodies in the instant of greatest compression. A British philosopher, nullius addictus jurare in verba magistri, asked, What will be the case of two encountering atoms of matter? Without calling them hard, we must conceive that they acquire their changes of motion in the inftant of mutual contact, and that they acquire them totally, being 'ατομοι, indivisible. No answer has been given, or indeed can be given, but what implies the same difficulty. From all that has been said, we must conclude, that this branch of mechanical philosophy is not put, by those philosophers, into the condition of an elementary foundation of clear and demonstrative science; that the transfusion, or transference, either of force or motion, is not a thing of which we have a diftinct conception; and that it necessarily leads us into very untenable doctrines. Far less does it seem safe for us to confide fo much in its clearness and certainty, as to affirm, that impulsion is the fole moving force in mechanical nature, and the fource of what we call pref-

> All this difficulty and obscurity has arisen from our arrogant notion, that we are competent judges of first principles; whereas we must acknowledge, that we can only perceive fuch as are properly related or accommodated to our intellectual powers: these powers, being specific and peculiar, cannot judge of principles of the first class, but of those only that are fuitably compounded. We can never know or comprehend any effential property of matter-we can only know the relative properties of fuch matter as we fee.

Therefore let us quit entirely the barren and trackless Therefore fields of abitraction, and rest fatisfied with contemplating what the Author of Nature has exhibited to our view, and fuch as he has been pleafed in his wildom to exhibit it. We grant that there are no bodies open to our inspection which are perfectly hard, receiving finite changes of motion in an instant. It has not pleafed God to put any fuch within our reach. When God Impulsion, created matter, it was with the purpose of forming a beautiful universe of this matter. He therefore gave it properties which fitted it for this purpose. It is this matter only that he has exposed to the wondering view of man. Thanks to his bounty, he has also given us properties of mind, by which this adaptation, when perceived by us, becomes a fource of dignified pleafure to the observer .- A Newton, to whom " Jovis omnia plena," a Daniel Bernoulli, were rapt almost into ecstacy by a fingle atom, when they observed how its properties, and only fuch properties, fitted it for making part of a world, which

> Unwearied, and from day to day, Should its CREATOR's power display.

Let the unhappy La Place confider these properties, which ensure the permanency of the folar system through ages of ages, as proofs of fatalism, as qualities effential to matter. But this Gallic torch effaces the bloom of life from the universe, the expression of the Supreme Mind which shines from within; and it spreads over the countenance of Nature the ghaftly paleness of universal death. But let us Britons rather follow the example of our illustrious countryman, and folace ourfelves with every discovery which tends to quicken our perception of Nature's animated charms. Let us liften to the conjectures of him who had already discovered fo many, and who endeavoured to remove the veil which concealed the rest.

Newton, in his maturity of judgment, after having Moving collected much information from his unwearied expe-powers are collected much information from his unwearied experiments in magnetism, in chemistry, in optics, &c. faid, all matter. that "he strongly suspected, that, in the same man-Newton's ner as the bodies of the folar fystem were connected conjecture by gravitation, so the particles of sublunary bodies improved were connected together, and affected each other, by vich. means of forces which acted at fmall, and, in many cases, insensible distances; producing the phenomena of cohesion, in all its forms of hardness, elasticity, ductility, foftness, fluidity, by which their mechanical actions on each other were modified and regulated." Father Boscovich, one of the first mathematicians of Europe, was the first who gave this conjecture of Newton's the attention that it so highly deserved. Other writers indeed, fuch as Keill, Freind, Boerhaave, &c. took occasional notice of it, and even made some use of it in their attempts to explain some complicated phenomena of nature. But they were fo careless in their employment of Newton's conjecture, fo completely neglected his cautious manner of proceeding, indulged fo wantonly in hypothetical affumptions, and reafoned fo falfely from them, that they brought his conjecture into discredit. Boscovich, on the contrary, copied Newton with care, and fecured his progrefs as he advanced by the aid of geometry; establishing a fet of uncontrovertible propolitions, which must be the inevitable refults of the premises adopted by him. He then proceeded to compare these with the phenomena of nature; and he shews that the coincidence is as complete as can be defired. All this is done in his Theoria Philosophia Naturalis, first published at Vienna in 1759. We have given a very short account of it in the article Boscovich, Suppl.; but it hardly goes beyond the enunciation of the general principle, and the indication

ion. of its applicability to the purposes intended. His application to the production of motion by the collision of bodies, is peculiarly satisfactory. But as the work is written chiefly with the view of gaining the approbation of persons well instructed in natural philosophy, it can hardly be called an elementary work, or be employed for the instruction of persons entering on the study. We shall attempt to explain this important law of mechanism in a way that will give our readers a distinct notion (and, we apprehend, a just one) of the procedure of Nature in all the cases of impulsion that we can observe. We hope to do this, by considering the changes of motion produced by moving bodies in a certain feries of familiar cases, where the procedure of nature may be diffinely observed, and where it is uniformly conceived by every fpectator; and which will gradually lead the mind to those cases where the procedure is not observed with distinctness: but the similarity to the former case is concluded by so fair analogy, that we imagine no person will controvert it. We shall begin by attending to the manner in which two magnets in motion affect each other's motions; a phenomenon that is familiarly known in the general, although, perhaps, few perfons have attended to it mi-

F e xxix.

? nets.

Let us, therefore, suppose two magnets, A and B (fig. 1.) equal in weight (in the first instance). Let them be made to float on water, by placing them on pieces of cork. Let them be placed with their north poles touching each other. Let A be held fast, and let B be at liberty to move. We know that it will gradually recede from A, with a motion that would continually accelerate, were it not for the refistance of the water. What is the inference drawn from this appearance? Surely this, that either a moving power, inherent in A, repels B, or that B avoids A, by an evalive power inherent in itself. It is immaterial for our purpose which opinion we adopt. Let us fay that A repels B. This admits more concise language than the other. If we prevent this motion of B by means of a very flender spring applied to its remote end, we shall observe that the fpring is bent back a little, just as if we were puthing away the magnet gently with the finger; and we observe, that the bending of the spring is so much the greater as B is nearer to A. We can judge of the intensity of the force by which B is actuated, by the bending of the spring - This force is equal to the weight of any body that will bend the spring to the same degree. This force is analogous, therefore, to the weight, the pressure of gravity, and we may call it a pressure, and measure it by grains weight. Every force that can bend a spring will move a body. This is a well known fact. Therefore it is next to certain, that it is this force which causes B to recede from A; nay, if we compare the motion of B with what should refult from the action of a force having this very intenfity, and varying in the fame manner by a change of diftance from A, taking in the diminution which the refiftance of the water must occasion, we shall find the motions precifely the fame. All this can be discovered by DYNAMICS, no 95, &c. Therefore we must conclude that this, and no other, is the cause of the recess

If, instead of placing B in contact with A, we place it at a distance from it, and push it toward A with an

initial velocity, fomewhat less than it would have ac-Impulsion. quired in that place by its recess from A, we shall find that it will approach A with a motion gradually retarded, till it stop at a small distance from A; and will now recede from it again with an accelerated motion. In short, we shall find that its whole motion to and from A is precifely the same with what results from a fimilar computation by n° 95. of DYNAMICS.

The whole of this phenomenon is conceived by every beholder, who has not imbibed fome peculiar theory of a stream of impelling fluid, as the indication and effect of a repulfive force exerted by A on B, or of a quality

of B, by which it recedes from A.

If now B be held fast, and A be set at liberty, it is observed to be repelled by B, or to recede from B, in

the fame manner, and with the fame force.

Thus, the two magnets appear to affect each other's motions, and are thought, and faid, by all to repel each other. - The effect appears curious, but excites no farther thought in most minds: it is only the speculatist that begins to suspect that he has not conceived it pro-

Now, let us suppose that B is assoat on the surface of the water, and at reft; and that A is pushed towards it, by a fingle stroke, causing it to move so moderately that it shall not strike B, but have its motion destroyed by the repulsion before it reaches it; and let us farther suppose, that the initial velocity of A was exactly measured—the fact will be as follows. As foon as A comes within a certain distance of B, its motion begins to be affected; it gradually diminishes, and at length it ceases entirely, and A remains ever after perfectly still. But it is also observed, that in the inflant that A flackens its motion, B begins to move; that it gradually accelerates in its motion, and at last acquires the initial velocity of A, with which it proceeds, till the refistance of the water brings it to reft, perhaps at a confiderable distance from A. This experiment is very amusing, and the initial velocity of A may be increased in each succeeding trial, till at last it strikes B. Even then the general appearance remains the same: A is brought to rest and remains at rest, neither refiling nor advancing forward; and B moves off with the initial velocity of A. What we wish to be particularly noticed is, that as long as the initial velocity of A is less than a certain quantity (depending on the strength of the magnets), the motion is communicated to B, or, to express it more cautiously, motion is produced in B, without any thing happening that can get the name of impulsion with propriety. In the ordinary conceptions and language of mankind, impulse always supposes actual contact; and impulsion is equivalent to a blow or a stroke. Both of these are indeed metaphorical terms, as well as impulsion. Perhaps the word "to hit," expresses this particular cafe more purely, and it is perhaps without any figure, and is the appropriate word. We do not speak at present of the conception and language of philosophers, but of persons taking an unconcerned view of things, without any intention of speculating farther about the matter.

Appearances perfectly fimilar are observed in electrified bodies. If we hang two equal bunches of very light downy feathers by two equal linen threads, fo as to hang close by each other like pendulums without

Impulsion touching, and if, after having electrified them fo that they repel each other to fome diffance, we draw one of them, which we shall call A, considerably aside from the perpendicular, and then let it go to fwing like a pendulum; we shall observe, that instead of accelerating till it reach the lowest point of its vibration, its motion will be retarded; it will stop entirely when its thread is perpendicular, and will remain at reft. In the mean time, the other bunch B will acquire motion, which will gradually increase till it equal the motion of A in its maximum state; and with this it would proceed for ever, were it not rifing like a pendulum in the arch of a circle. The general fact is the fame as in the cafe of the magnets. The moving body is brought to rest, in which state it continues, and the quiescent body moves off with an ultimate velocity, equal to the initial velocity of the other; and all this happens without contact or impulsion, but is produced by the mutual repulsion of the electrified bodies.

If this general fact be compared with what happens in the collition of two billiard balls, it will be found perfectly fimilar in every respect, but that of the contact and the impulsion, properly fo called. The impelling ball is brought to rest, and remains at rest; and the impelled ball moves off with the velocity of the im-

pelling ball.

This being the case, it is plain that we may derive fome information from the motion of the magnets, that must greatly assist us in our conceptions of what passes in the rapid, if not instantaneous, production of motion in a billiard ball, by hitting it with another. In the case of the magnets, we perceive, and can discriminate, a progressive train of changes, which terminate in a final change, perfectly similar to the change in the impulsion of the billiard ball. This will justify a very minute attention to, and statement of, all the circum-

First cafe. toward B at reft.

stances. Let us attend to the process of this operation, and the production of motion in the magnet originally at reft, and the abolition of it in the one originally in motion; and let us reflect on what passes in our minds when we try to explain it to ourselves. The trials mentioned at first, when one magnet was held fast, shew us that each magnet repels or avoids the other, and that this action is found to be equal on both fides, producing equal compression of the spring employed for ascertaining the intensity of this repulsion when the diflances are the fame. This is the fact. It is no lefs a fact, that equal moving forces, fuch as equal preffures must be supposed to be, produce equal changes of motion in their own direction. Therefore, as foon as A comes to fuch a distance from B that the mutual action takes place, both magnets are affected, and equally affected; that is, equal changes of motion are produced on each, but in opposite directions. The motion of A is diminished, perhaps tooth part, in toth of a second, and (let it be carefully remembered) while A passes over a certain space, suppose the 10th of an inch. During this small portion of time, B acquires as much motion as A lofes. This is not the motion loft by A. This is inconceivable; for motion is not a thing, but a condition. But it is an equal degree of motion. B has passed over a small space during this time, perhaps the 50th part of an inch, with an almost imperceptible

motion, that is gradually accelerated from nothing. Impulian. Since A is moving fafter than B, it must still gain upon it; and therefore the mutual repulsion will increase: and in the next toth of a fecond this force will take another and greater portion of A's original velocity from it, and will add a greater velocity to that already acquired by B. And thus, in every succeeding minute portion of time, the motion of A will be more and more diminished, and that of B as much increased, by the equal, though continually increasing, simultaneous repulsions acting in opposite directions. It is evident, that it is possible that the velocity of A may be so much diminished, and that of B so much increased, that the remaining velocity of A shall be just equal to the acquired velocity of B. Till this happens, the distances of the magnets have been continually diminishing; for A has been moving fafter than B, and gaining on it. If the operation of the mutual repulsions could be stopped at this inflant, both magnets would move forward for ever with equal velocities.

It is of particular importance to know what this They accommon velocity is. This is determined by our previ-quire a ous knowledge, that the magnets repel or avoid each common other with equal forces. These forces may vary by a velocity x; variation of distance; but the force acting on A is always equal and opposite to the force acting at the same time on B. This is the uncontroverted fact (the authority for which shall soon be considered). These equal forces must therefore produce equal and opposite changes of motion. The motion acquired by B is equal to that loft by A. But the magnets being suppofed equal, and moving with equal velocities, they have equal quantities of motion. Therefore the motion acquired by B, or that loft by A, is equal to what remains in A; that is, A has loft half of its motion, and therefore half of its velocity; or the common velocity is half

of the primitive velocity of A.

It was for the fake of a somewhat easier discussion that we supposed the magnets to be of equal weights. But it is almost equally easy to ascertain what this common velocity will be in any other proportion of the quantities of matter in A and B. It is a matter of unexcepted experience, that whatever be the weight or ftrength of two magnets, their actions on each other are always equal. Therefore the fimultaneous force must always produce equal changes of motion in the two bodies. But the change of motion is expressed by the product of the quantity of matter and the change of velocity. Therefore let A and B represent the quantities of matter in the magnets; and let a be the primitive velocity of A, and x the velocity which obtains when both are moving with one velocity. The velocity loft by A is a - x. Therefore we must have $B x = A \times a - x$,

= Aa - Ax; and Aa = Ax + Bx, = $A + B \times x$, and $x = \frac{Aa}{A + B}$. The common velocity is therefore ob-Namely, tained by dividing the primitive quantity of motion by the A+ fum of the quantities of matter.

This may be conceived more compendiously in another way. Since B acquires as much motion as A lofes, the whole quantity of motion is the fame as before: Therefore the common velocity must be had by dividing this quantity of motion by the whole quantity

Phillion of matter. But we wished to make the reader keep his attention fixed on the steps of procedure, and see the connection of each with the causes.

We shall find that this period of the whole process, namely, the moment when both bodies have acquired a common velocity, and the precise magnitude of this velocity, are points of peculiar importance in the doctrine of impulfion; indeed they almost comprehend the whole of it.

But this is a state that cannot continue for a moment in the example before us. The repulsive or evasive forces are still acting on both magnets, and still diminish the motion of A, and equally increase the motion 1 nets fc- of B. Therefore the velocity of A, in the very next moment, must be less than that of B; and B has, during this moment, gained on A, or has removed farther from it. This continues; A is still retarded, and B is accelerated; and therefore gains more and more upon A, or separates farther and farther from it. This must continue as long as the mutual repulsions are supposed to act. If we suppose that the fensible action of these forces is limited to some determinate distance, the mutual action will ceefe when B has got to that distance before A. We may call it the inactive distance. After this, A and B will proceed with the velocities which they have at that instant. Let us inquire into these final velocities; and thus complete our acquaintance with the process.

We see (and it is important) that the magnets are in their state of greatest proximity at the instant of their ie commoving with a common velocity, and that after this on velothey gradually separate, till they are again at their iny is ate instant active distance. During this separation they attain diflances from each other equal to what they had during the period of their mutual approach. At these distances the repulsions are the same as before, and act in the same direction. Therefore, in each moment of separation, and at each distance, A fustains the same diminution, and B gets the same augmentation of its motion, as when they were at the fame distance in the period of their mutual approach. The fums total, therefore, of these equal augmentations and diminutions must be equal to the augmentation and diminution during the approach. Therefore the whole diminution of A's mo-

tion must be double of the diminution sustained during the approach; and the whole augmentation of B's motion must, in like manner, be double of that acquired during the approach of A. Hence we easily see, that when the magnets are supposed equal, A must be brought to rest; for in the period of approach it had

loft half of its velocity. It must now have lost the whole. For fimilar reasons B must finally acquire the primitive velocity of A; for in the inflant of greatest proximity, it had acquired the half of it.

Thus we see, that the equal mutual repulsions are precisely adequate to the production of the changes of adequate to motion that are really observed; and must therefore be admitted as the immediate causes of these changes.

It is equally easy to ascertain the final velocities when the magnets are of unequal fizes; for the equality of their mutual repulsions is not affected by any inequality of their magnitudes. Their feparations, and areunequal the changes of motion during these separations, will be the same with their approaches and the corresponding changes of motion; and the whole change on each will be double of the change sustained at the instant of SUPPL. VOL. I. Part II.

greatest proximity and common velocity. Hence we Impulsion. learn, that the final velocity of B is 2x, or $\frac{2Aa}{A+B}$; and the final velocity of A is $\frac{\overline{A} - \overline{B} \times a}{A + B}$. For the primitive velocity of A being a, and the common velocity, in the inflant of nearest approach, being $\frac{A a}{A+B}$ the loss of velocity is $a - \frac{A a}{A+B}$, $= \frac{A a + B a - A a}{A+B}$, $= \frac{A a + B a - A a}{A+B}$, $=\frac{B a}{A+B}$. Therefore the final lofs of velocity is $\frac{2 B a}{A+B}$? and the remaining final velocity is $a - \frac{2 B a}{A + B}$,

 $\frac{A a + B a - 2 B a}{A + B}, = \frac{\overline{A - B} \times a}{A + B}$

Let us, in the next place, fee what will be the refult when both of the magnets are in motion at the be-II. Cafe. ginning of their inutual action. And, first, let both Both magmove in one direction. Let A, moving with the vertion in one locity a, overtake B, moving in the same direction with directionthe velocity b, less than a. Moreover, let the velocities a and b be fuch, that their difference a - b is somewhat less than the sum of the velocities a and B, which the mutual repulsions of the magnets would generate in them, if the magnets were placed in contact, and allowed to recede from each other till they get beyond their acting distance.

These things being premised, let the magnets be set in motion in the same direction with the above-mentioned velocities a and b. The magnet A must gain on B, and at last come so near it, that the mutual repulfions begin to act on both. It is plain, that the motion of A will be diminished, and that of B increased, by equal quantities, during every minute portion of the time of their mutual action. It is also evident, that the velocity of A may be so much diminished, and that of B fo much increased, that they shall be rendered equal. Also this will happen before the magnets touch one another; because the original difference of their quantities of motion has been supposed less than the motion which the repulsive forces are able to generate or extinguish, by acting on them through the whole distance which gives occasion to their action. 'Therefore the difference of the velocities is less than the sum of the velocity a, which the mutual repulsion can take from A, and the velocity &, which it can give at the fame time to B. The magnets will gradually approach, and the mutual repulsions, and confequent diminution of A's, and augmentation of B's motion, will gradually increase, till the fum of a and B is just equal to the difference of a and b; that is, till the bodies are moving with one velocity. If the mutual repulfions were annihilated at this inflant, the bodies would move forward with this common velocity. What this is we determine with great facility, as we did in the former cafe: Because the repulsions produce equal and opposite changes of motion in the magnets, as much is taken from $A \times a$ as is added to $B \times b$; and the fum of $A \times a$, and $B \times b$, is equal to the fum of $A \times x$ and $B \times x$, or $\overline{A + B} \times x = A \times a + B \times b$, and $x = \frac{A \cdot a + B \cdot b}{A + B}$.

Therefore

Impulsion. Therefore the common velocity is had by dividing the fum of the primitive quantities of motion by the sum of the quantities of matter.

Common

But the repulsive forces continue to act as in the for-Aa + Bb mer case. The motion of A is still more diminished, A+B and that of B augmented: Therefore the velocity of B but the must now exceed the velocity of A, and the magnets magnets se-must separate, and Reasoning in the same way as in the the change former case, it is evident that the mutual action does is doubled not cease till the magnets have separated to their inactive distance from each other, and that the whole change of motion in each is double of the change that it had fustained when they were in their greatest proximity, and moving with a common velocity. considerations enable us to ascertain the final state of each. The common velocity is $\frac{A a + A b}{A + B}$. fore the change made on the velocity of A, at the inflant of greatest proximity, is $a - \frac{A \ a + B \ b}{A + B}$, or =

 $\frac{B \times a - b}{A + B}$, and the final velocity of A is a - b $\frac{2 B \times a - b}{A + B}$. In like manner, the change produced

on the velocity of B is = $\frac{Aa + Bb}{A + B} - b$, or = +

 $\frac{A \times a - b}{A + B}$, and the final velocity of B is b + b

 $\frac{2 \text{ A} \times a}{\text{A} + \text{B}}$. We may also obtain the final velocity of each, by taking its initial velocity from twice the

common velocity

If, in this example of two magnets in motion, we suppose them of equal weight, we shall find that they will finally proceed with exchanged velocities. For when A = B, it is plain that $a - \frac{2B \times a - b}{A + B}$ is $= a - 1 \times a - b$, = a - a + b, = b: and $b + 2A \times a - b$ $\frac{2 \text{ A} \times \overline{a - b}}{\text{A} + \text{B}}$ is $= b + 1 \times \overline{a - b}$, = b + a - b, = a.

This case is easily subjected to experiment, and will be found fully confirmed, if we take into account the retardations occasioned by the resistance of the water to

the motions.

Let us, in the next place, suppose the magnets to be moving in opposite directions with the velocities a moving in and b; and (in order that the magnets may not strike each other) let the sum of a and b be less than the sum of a and B, which the repulsions of the magnets would produce by repelling them from contact to their inactive distance.

As foon as the magnets arrive at their acting distance, their mutual and equal repulsions immediately begin to diminish both of their motions; and in any minute portion of the period of their approach, equal quantities of motion are taken from each. It is evident, that if the primitive quantities of motion have been equal; that is, if A and B have been moving with velocities reciprocally proportional to their quantities of matter, then, when the motion of one of them has been annihilated by their mutual repulsion, the motion of the other will be destroyed at the same time, and both will

be brought to rest. Were the repulsions annihilated at impulsion, this instant, they would remain at rest. But because those forces continue their actions, the magnets will feparate again, regaining, at every distance, the velocity which they had, when at that distance, during their mutual approach; and when they have reached their inactive distance, they will have regained each its oilginal momentum and velocity, but in the opposite direction. This needs no farther comment; but must be kept in mind, because this case has a precise counterpart in the collision of folid bodies, meeting each other in opposite directions with equal momenta. But if the momentum of one exceed that of the other, thus, if $A \times a$ be greater than $B \times b$, then, when the magnet B is brought to rest, A has still a momentum remaining equal to A a - B b. Having therefore a certain velocity, while B has none, it must approach fill nearer to B, and a still greater repulsion will be exerted on B than if A had also been brought to rest, but still repelling B. Since B is now acquiring motion in the direction opposite to its former motion, and A is still losing motion, a time must come when the motion of A is fo much diminished, and that of B so much augmented, that they are moving with a common velocity in the direction of A's primitive motion. The reasoning employed in the foregoing examples shew us, that, in the prefent case also, this state of common velocity is also the state of the greatest proximity, and that the magnets separate again, till they attain their distance of inaction, and that the total change in each is double of what it was in their state of greatest proximity.

To find this common velocity, recollect, that when the momentum of B was extinguished, that of A was Common ftill = A a -- B b. From what has been already faid velocity = on the other cases, we know that when the common $\frac{Aa}{A} = \frac{Bb}{B}$, velocity obtains, the whole momenta are still equal to $\frac{A}{B} = \frac{Bb}{B}$ velocity obtains, the whole momenta are still equal to but the A a - B b. Therefore the common velocity x must be change is $\frac{Aa - Bb}{A + B}$ the fubfe-

The velocity lost by A must therefore be a quent sepa- $\frac{A a - B b}{A + B}$, $= \frac{B \times \overline{a + b}}{A + B}$, and the final velocity will

be $a = \frac{2 B \times \overline{a+b}}{A+B}$. The final motion of A will be in the same direction as at first, if a be greater than $\frac{2 \text{ B } \overline{a+b}}{\text{A}+\text{B}}$, otherwise it will be in the opposite direction.

In like manner, the change of velocity in B is b+ $\frac{A a - B b}{A + B}$, because the former velocity b is destroyed,

and the new velocity is $\frac{A a - B b}{A + B}$ in the opposite di-

rection. This is $=\frac{A \times a + b}{A + B}$, and the final velocity

of B is = $b - \frac{2 \text{ A} \times \overline{a + b}}{\text{A + B}}$.

Thus we have shewn, in the case of magnets acting The chanon each other by repullive forces, or actuated by forces tion in the equivalent to repulfive forces, how changes of mo-magnets tion are produced, which have a great refemblance to are fimilar those which are feen in the collision of folid bodies. to those in The motions which obtain in the inftant of greateft the colliproximity dies.

31 Magnets opposire directions.

in tion, proximity are precifely fimilar to what are observed in the collision of unelastic bodies. Their common velo-

city after collision is always = $\frac{A a + B b}{A + B}$,

 $\frac{A a - B b}{A + B}$, according as the bodies were moving in the fame or in opposite directions. The final motions of the magnets are also precifely fimilar to what are obferved in the collision of perfectly elattic bodies. We took the instance of magnets, because the object is familiar; but we can substitute, in imagination, an ab-Aract repulsive force in place of magnetism, and we can affign it any intenfity, and any law and limits of action we please. We can imagine it so powerful, that although its action be limited to a very small, and even infensible distance, it shall always reduce the meeting bodies to a common velocity before they come into actual contact; and therefore without any real impulsion, as impulsion is commonly conceived.

There are some farther general observations that may be made on those motions which are of importance.

1. We see that the changes of motion, and conse-Techan-quently the actions, are dependent on the relative moproual tions only, whatever the absolute motions may be: For to e rela-changes are always as a - b when the bodies are moving in one direction, and as a + b when they are moving in opposite directions. Now $a \pm b$ is the relative

2. The change of velocity in each of the two bodies is inverfely as its quantity of matter, or is proportional p ally as is inversely as its quantity of matter, or is proportional dipantity to the quantity of matter in the other body. The

changes in A and B are $\frac{B \times a \pm b}{A + B}$ and $\frac{A \times a \pm b}{A + B}$. tirof mat-

The changing forces being equal on both fides, produce equal changes in the quantities of motion; and therefore produce changes of velocity that are inverfely

as the quantities of matter.

3. During the whole process, the sum of the momenta, or quantities of motion, remains the same, if the bodies are moving in one direction: if they are moving in opposite directions, it is the difference of momenta that remains the same; for in every instant of the process equal changes of momentum are made in opposite directions. When the motions are in the same direction, as much is taken from the one as is added to the other; and therefore the fum remains unchanged. When the motions are in opposite directions, equal quantities are taken from both; and therefore the difference remains unchanged. This is called the CONSERVATIO MOMEN-TORUM; and it is usually enunciated by faying, that the quantity of motion, estimated in one direction, is not changed by the equal and opposite actions of the bodies. This is a particular case of a general law affirmed by Des Cartes, that the quantity of motion in the universe remains always the same when estimated in any one direction.

4 When the whole process is completed, the fum of the products made by multiplying each body by the fquare of its final velocity, is equal to the fum of the products made by multiplying each body into the square of its initial velocity. For when the process is completed, the two bodies are at the same distance from each other as when the mutual action began. There-

equal space, and in every similar point it has been act. Impulsion. ed on by an equal force (although this force be different in different points of this space). Therefore, in every instant, the timultaneous products of the quantity of matter by the momentary variation of the square of the velocity are equal on both fides; and therefore the prodness of the quantity of matter by the whole change of the square of the velocity are also equal on both sides. See DYNAMICS, Suppl. no 95. and 110. where v v = $\frac{f_s}{m}$; and therefore $m vv = f_s$, and $m \times V^2 - v^2$, or

 $n \times v^2 - V^2 = \int f s$. Now, fince these changes are in opposite directions, as much is added to one product as is taken from the other, and the sum of the products of the quantities of matter by the squares of the final velocities, is equal to the fum of the products of the fame quantities of matter by the squares of the initial

This is a particular case of the famous CONSERVATIO These two VIRIUM VIVARUM, claimed as a mighty discovery by theorems the partizans of Leibnitz, and aferibed to him; but principles, he has no claim whatever to the discovery. It was but general communicated to the Royal Society of London in 1668 facts. by Huygliens, as one of the general laws of impulsion, obtaining in what he calls hard bodies. Several of the Leibnitzian school, indeed, extended it farther than Huyghens had done; some of them indeed very lately. The observation of this general law was soon applied to many excellent purposes in the solution of very intricate problems; because it often faved the trouble of tracing the intermediate steps of a complicated process. Affured that these products were invariable, the mathematician found it an eafy matter to state what conditions of the queltion infured this equality of products; and thus the problem was folved. In this manner Daniel Bernoulli gives most elegant folutions of some, otherwife almost intractable, problems in Hydraulics. For fuch reasons, as a mighty aid in mechanical investigation, the discovery of Huyghens is extremely valuable. Its merit in this respect is perfectly similar (though perhaps fomewhat greater) to Des Cartes's observation of the conservatio momentorum. It is also like the observation or discovery of Maupertuis, which he calls the law of smallest action (indeed it is the same under a different aspect), or La Grange's law of virtual velocities, or D'Alembert's law of equilibrium of action; -all of these are general facts, laws by which the changes of motion are observed to proceed. But their authors have vaunted them as principles, as causes, from which to conclude effects; whereas they are really inductions from particular inflances. We must also observe, that this law of conservatio virium vivarum was not deduced either by Huyghens or any of the Leibnitzian school, by reasoning from more general principles. It was an expifcation of fameness in events, diversified by other circumstances. We do not recollect any author who has given what can be called a demonstration of it, deducing it from principles or laws still more general. We apprehend, that the present case of its truth has been fo demonstrated by us. The principle is, that " a moving force is to be measured by the change of motion produced by it:" And the law to which this principle fore, during the process, each body has passed over an is applied is, that "the mutual repulsions of magnets

37 ONSER TIO VI-UM VI IRUM.

A reci-

36 (NSER-

110 Mo.

Impulsion. are equal and opposite;" and the application is made by means of the "39th proposition of the first book of Newton's Principia." Our principle, which is the same with Sir Isaac Newton's fecond law of motion, is really an axiom of human thought. The proposition is the confequence logically drawn from this axiom; and the law of magnetism is an observed fact. We hope to thew by and bye, that this proposition, which is our nº 95 of Dynamics, is found to obtain in every instance that has been or can be given of the conservatio virium vivarum, and that this confervatio is only another way of expressing the proposition. Having done this, we shall not think ourselves chargeable with vanity when we fay, that we have given the first demonstration of this famous law. We cannot refuse ourselves some satisfaction at having done this; because it has been so highly esteemed, chiefly for the support derived from it for the Leibnitzian measurement of the force of moving bodies by the fquare of the velocity which it communicates; whereas it is the logical consequence of the force being proportional to the simple velocity. We have only taken a weapon out of the hands of a plunderer, and reltored it to its lawful owner, Sir Isaac Newton. Non ita certandi cupidus, quam propter amorem: For we must

> Tu pater et rerum inventor, tu patria nolis Suppeditas precepta, tuisque ex, inclute, chartis Floriferis ut apes in faltilus omnia libant, Omnia nos itidem depascimur aurea dicta Aurea, perpetua semper dignissima vita.

We trust that our reader will not think that this minute discussion of the mutual actions of magnets or other repelling bodies, in which we have engaged him, has been thrown away, fince it has enabled us to apprehend clearly a case of two such general laws as the confervatio momentorum, and the confervatio virium viva-

Vis viva bodies.

5. In the moment of greatest vicinity and common velocity, there is a certain determinate lofs of the vicollision of res vive, or products of the matter by the square of the velocity; and this loss is proportional to the fquare of the relative motion. The vires viva, at the commencement of the mutual action, are $= A a^2$ the commencement of the mutual action, are $= Aa^{a} + Bb^{2}$ (1.). In the moment of greatest proximity, the quantity of matter A + B is moving with the common velocity $\frac{Aa + Bb}{A + B}$; therefore the vires vive are $= \overline{A + B} \times \frac{\overline{Aa + Bb^{2}}}{\overline{A + B^{2}}} = \frac{\overline{Aa + Bb^{2}}}{\overline{A + B}}$, = $\frac{A^{2} a^{2} + B^{2} b^{2} + A B \times 2 a b}{A + B}$ (II.). I. $\times \overline{A + B} = A^2 a^2 + B^2 b^2 + A B \times \overline{a^2 + b^2}$. II. $\times \overline{A} + \overline{B} = A^2 a^2 + B^2 b^2 + A B \times 2 a b$

Loss of vis viva = $\frac{A B}{A + B} \times \overline{a - b^z}$, a quantity Impulsion,

that is proportional to $a-b^2$, the square of the relalative velocity a - b.

Had the bodies been moving in opposite directions, then (II.) $\times A + B$ would have been $A^2 a^2 + B^2 b^2$ — A B \times 2 a b, and the difference from A $a^2 + B b^2$ \times A + B would have been = A B \times a + b^2 , proportional to the square of the relative velocity a + b.

Such is the fact; and we shall find it of importance Physical in the great debate about the force of moving bodies, cause of this Let us inquire into the physical or mechanical cause of it. Let us inquire into the physical or mechanical cause of it. In the moment of common velocity, the bodies are nearer to each other than they are at the beginning and at the end of their mutual action. Therefore (when they are moving in one direction) the body A, which follows, has been retarded through a space which is greater than the space along which the preceding body B has been accelerated. But, because the simultaneous forces acting on the bodies along these unequal spaces are always equal, the area which measures the diminution of the square of A's velocity (DYNAMICS, n° 95.) must exceed the area which expresses the augmentation of the square of B's velocity, and there must be a loss of vires viva. Now, we learned above, that the mutual action is the fame when the relative velocity is the fame; and therefore the approximation, which is the occasion of this action, must be the same. And it is demonstrated in Dynamics, no 95. that the area, whose abscissa is the space described, and ordinates the forces, expresses the fquare of the generated or extinguished velocity. This is evidently the relative velocity of the bodies, because they are brought to a common velocity in the instant of greatest proximity; that is, their relative velocity is

6. During the whole process, the common centre of the moposition or gravity (A) is moving uniformly with the tion of the velocity $\frac{Aa = Bb}{A+B}$. For the motion of the centre of centre of position is the average of the motion of every particle not chan. of matter in both bodies. A a is the sum of the mo-ged by the tions of every particle of matter in A, and B b is the mutual action of the motions of every particle in B, before the mutual actions began. Therefore A = 1 B. mutual actions began. Therefore Aa + Bb is the whole motions when the bodies are moving in the same direction with their different velocities. The number of particles is A + B: Therefore, if the whole motions be equally divided among all the particles, the velocity of each must be $\frac{A a + B b}{A + B}$. This is the ave-

rage motion, or the motion of the centre of position, deduced from the notion we wish to impress of the character of this centre, as the index of the position and motion of any affemblage of matter. This velocity may be deduced more easily from its geometrical pro-

(A) See the article Position in this Supplement; where it will be demonstrated, that the centre of gravity (determined in the usual manner) is the point by whose situation and motion we estimate with the greatest propriety the situation and motion of the assemblage, of which it is the centre: it is therefore called the CENTRE OF PO-SITION. The reader is only defired at prefent to recollect, that the centre of gravity, or position of two bodies, is situated in the line joining their centres; and that its distance from each is inversely as their quantities of matser; and that the distance and motion of the centre is the medium or average of all the distances or motions.

797

pulsion. perty. It is a point so situated between A and B, that its distance from each is reciprocally proportional to the quantities of matter in A and B, as is well known of the centre of gravity. It is equally plain, that when the bodies are moving in opposite directions, the ave-

rage velocity x must be $=\frac{A a - B b}{A + B}$. Thus we see, that the motion of the centre of position, before the

magnets have begun to act on each other, is the same with its motion when their mutual repulsion is the greatest; namely, at the moment of their greatest vicinity. It has continued the same during the whole procefs: For we have already feen, that the fum or difference of the momenta, or $Aa \pm Bb$, remained always the

fame; confequently $\frac{A}{A} = \frac{B}{B} \frac{b}{B}$, or x, the motion of

the centre, remains always the same. Therefore the proposition is demonstrated. It is, indeed, a truth much more general than appears in the present instance. If any number of bodies be moving with any velocities, and in any directions, the motion of the centre of position is not affected by their mutual, equal, and opposite, actions

40

e mo-

7. During the whole motion, the motion of the bons, in re-dies relative to each other, is to the motion of one of on to the them, relative to the centre of position, as the sum of the iprocally bodies is to the other body: For when they were moving with a common velocity, this velocity was the same with that of the centre; and they are then at rest, relative to each other, and relative to the centre. And because their distances from the centre are inversely as the bodies, their changes of distance, that is, their motions relative to the centre, are in the same proportion; and the fum of their motions relative to the centre is the same with their motions relative to each other. Therefore $\Lambda + B : A = a - b$: motion of B relative to the centre. Indeed we faw, that in their mutual action,

the change of B's motion was $=\frac{A \times \overline{a-b}}{A+B}$, and the

change of A's motion was $=\frac{B \times a - b}{A + B}$

Hence we learn, that while the centre moves unihe bodies formly, the bodies approach it, and then recede from it, with velocities reciprocally proportional to their quantities of matter. This will be found a very useful corolne rela-'e veloci- lary. We may also see that their final velocity of mutual recess is equal to that of their first approach, or, their relative motions are the fame in quantity after oached. the action is over as before it began, but in opposite

All these general facts, which are distinctly appreciable, and very perceivable, in this example of magnets, or electrified bodies, are equally appreciable in all cases of mutual repulsions, however strong these may be; and although the space through which they are exerted should be so small as to elude observation, and though the whole process should be completed in an in-

sensible moment of time.

It fearcely needs any comment to make it clear that the very fame changes of motion must take place, if a ring has solid body A should come up to another solid body B, at rest, or moving more slowly in the same direction, or moving in the opposite direction; provided that there pulfions. be a fpring interposed between them, which may hinder

A from striking B; for, as soon as A touches the Impulsion. fpring, it begins to press it against B, and, therefore, to compress the spring. It cannot carry the spring before it, without the spring's pushing B before it. Pref-fure on B is required for this purpose. This is supplied by that natural power which we call elasticity, which is inherent in the spring, whether it be in motion or at rest. It is not in action, but in capacity, faculty, capability, power, or by whatever name we may choose to express the posfession. The occasion required for its exertion is compresfion. This is furnished by the motion of A; for A cannot advance without compressing it. This inherent force of the spring is known to act with perfect equality at both ends, in opposite directions. It exerts equal and oppofite pressures on A and on B; it diminishes the motion of A, and equally augments the motion of B (if both are moving that way). A is retarded, and B is accelerated; A is still moving faster than B; and therefore the compression and the consequent reaction of the spring increases, and still more retards A and accelerates B. After some time, both bodies, with the spring compressed between them, are moving with equal velocities; the spring, however, is strongly reacting on both, and must now cause them to separate; still retarding A, and accelerating B-They must separate more and more, till the ipring regain its quiescent form, and its elastic reaction cease entirely. During its restitution, its pressures are the same as during its compression; therefore, the whole change produced on each of the bodies must be double of what it was when the spring was in its state of greatest compression, and the bodies were moving with a common velocity. In short, the whole process in this example must be precisely similar to that of the magnets in every circumstance relating to the

changes of motion in A and B. The common velocity must be $=\frac{A \ a \pm B \ b}{A + B}$. The final velocity of A must be $=a - \frac{2 \ B \ a \pm b}{A + B}$, and that of B must be $=a - \frac{2 \ B \ a \pm b}{A + B}$

 $b + \frac{2 \overline{A} = b}{A + B}$. The motion of the common centre

must be unaffected by the action of the spring, and the motion of each body, relative to the centre, must be reciprocally as its quantity of matter, &c. &c.

We apprehend that this process can scarcely be call-The chamed impulsion; A has not struck B. The changes of ges of memotion can scarcely be ascribed to forces inherent in A tion are or B, in consequence of their being in motion. Any by the inperson, not already warped by a theory, will (we herent forthink) ascribe them to a fertile them. think) aferibe them to a force inherent in the fpring; ces which inherent in it, whether at reft or in motion, and only connect the requiring a continued compression as the proper opportunity for its continued exertion. This fpring may be supposed to make a part of B, or of A, or of both; and then, indeed, the force may be faid to be inherent in either, or in both. But it is not the peculiar force inherent in motion, or in moving bodies only-it is the force of elasticity, inherent in part of the body, but requiring a continued compression for the production of a continued repressions. The effect of this reaction is modified by the very occasion of the compression. This may be the elasticity of another spring. In this case it will only compress that spring-It may be the advance of a body in motion; the reaction produces a retarda-

ofed

n inter-

which

44 Internal process of change through the fubftance of each body.

impulsion tion of that motion; it may be the obstacle of a quiescent body-it will give it motion; or, it may be the obstruction by a body moving more slowly away than the spring is pressed forward-it will accelerate that motion. Thus, in all these cases, we cannot help distinguishing the immediate cause of these changes of motion from the supposed force of a moving body. Nay, the process of motion is fimilar, even when we suppose that the spring is not a thing external to the body, although attached to it; but that the whole body, or both bodies, are fpringy, elastic, and therefore compressible. As soon as the bodies come into senfible contact, compression must begin; for we may suppose the bodies to be two balls, which will therefore touch only in one point. The mutual pressure, which is necessary in order to produce the retardation of A, and the acceleration of B, is exerted only on the foremost particle of A, and the hindmost particle B; but no atom of matter can be put in motion, or have its motion any way changed, unless it be acted on by an adequate force. The force urging any individual particle, must be precisely competent to the production of the very change of motion which obtains in that particle. Except the two particles which come into contact in the collision, all the other particles are immediately actuated by the forces which connect them with each other; and the force acting on any one is generally compounded of many forces which connect that particle with those adjoining. Therefore, when A overtakes B, the foremost particle of A is immediately retarded-the particles behind it would move forward, if their mutual connection were diffolved in that instant; but, this remaining, they only approach nearer to the foremost firiking particles, and thus make a compreftion, which gives occasion for the inherent elasticity to exert itself, and, by its reaction, retard the following particles. Thus each stratum (so to conceive it), continuing in motion, makes a compression, which occafions the elasticity to react, and, by reacting, to retard the flratum immediately behind it. This happens in fucceffion: the compression and elastic reaction begin in the anterior stratum, and take place in succession backward, and the whole body gets into a flate of compref. sion. Things happen in the same manner in B, but in the contrary direction, the foremost strata being the last which are compressed. All this is done in an in flant (as we commonly, but inaccurately speak), that is, in a very small and insensible moment of time; but in this moment there is the same gradual compression, increase of mutual action, greatest compression, common velocity, subsequent restitution, and final separation, as in the case of bodies with a slender spring interposed, or even in the case of the mutually repelling magnets. In all the cases, the changes of motion are produced by the elasticity or the repulsion, and not by the transfusion of the force of motion. The changing force is indeed inherent in the bodies, but not because they are in motion; the nfe of the motion is to give occasion, by continued compression, for the continued operation of the inherent elafticity. The whole procels may be very distinctly viewed, by making use of bodies of small firmness, such as foot-balls, or blown bladders. If blown bladders are used, each loaded with - dend, or formething that will require more force, and

confequently more compression to impel it forward; we Impulsion shall observe the compression of both to be very considerable, and that a very fenfible time elapses during the process of collision. This may even be observed very distinctly in a foot ball, which is always seen to rest a little on the toe before it flies off by the stroke. When one foot ball is strongly driven against another, they plainly adhere together for some time, and then the stricken ball flies off.

If we return to the example of the two balls with the spring interposed, we may make some farther useful observations. When the spring is in its state of greatest compression, and the balls are moving with a common velocity, we can suppose that the spring is arrested in that fituation by a catch. It is evident that the two bodies will now proceed in contact with this velocity.

which we have shewn to be $=\frac{A \ a \pm B \ b}{A \ b}$

Now, in the constitution of such masses of tangible Nature of matter as we have the opportunity of subjecting to our experiments, we find a flate of aggregation which very elasticity. much refembles this. Some bodies are almost perfectly elastic, that is, when their shape is changed by external pressure; and that pressure is removed, they recover their former shape completely, and they recover it with great promptitude. Glass, ivory, hard steel, are of this kind. But most bodies either do not recover it completely, or they recover it very flowly—fome hardly recover it at all. A rod of iron will, when confiderably bent, not nearly recover its shape; a rod of lead still less; and a rod of soft clay will hardly recover it in any degree. These, however, are but gradations of one and the same quality: if the quiescent form of a body is very little disturbed, it will recover it again. Thus, a common foft iron wire of No 6. and 12 inches long, if twifted once round, will return completely to its original form, and will allow this to be repeated for ever; but if it be twifted 1 turns, it will untwift only 1 : and in this new form, it will twift and untwift one turn as often as we please. Even a rod of fost clay, Toth of an inch in diameter, and 7 feet long, will bear one twift as often as we please; but if twifted 4 times, will untwift itfelf only one turn, and will do this as often as we choose. In short, it appears that the particles of bodies, usually called unelastic, will admit a small change of distance or fituation, and will recover it again, exhibiting perfect elafticity, in opposition to very small forces; but if they are forced too far from this fituation, they have no tendency to return to it completely, but find intermediate fituations, in which they have the very fame connections with the furrounding particles; and in this new fituation, they can again exhibit the fame perfect elasticity, in opposition to very small forces. Mr Coulomb conceives fuch bodies to confit of elastic particles: they manifest perfect elasticity, so long as the forces employed to change their shape do not remove the particles from their present contacts; but if they are removed from thefe, they slide on to other fituations, where they again exhibit the fame appearances. To understand this fully, the reader may confult the article Boscovich of this Supplement-The fact is fufficient for our prefent purpose. Now, in this variable constitution, where the particles may take a thousand different fituations, and still cohere, it is plain, that when a

pullion, body has been dimpled by compression, the particles have nothing to bring them back to their first situation when the compressing force is removed: the utmost elasticity to be expected, is that which will not extend to one shift of situation; therefore, the restitution is altogether infenfible. This is the cafe with all foft bodies, fuch as clay—the same quality is manifested in all ductile bodies, fuch as lead, foft iron and fteel, foft copper, foft gold. 46] :ct of

Now let one of these bodies strike another. The compression, or the sliding of the particles over each other, requires force, or mutual preffure - This being accompanied by a reaction perfectly equal, must operate, during the compression, precisely as the equal repultive forces did. It will take as much momentum from A as it gives to B; so that A a \pm B b will remain invariably the fame, and a common velocity will at last ob-

t colli-

tain, $=\frac{A \ a \pm B \ b}{A + B}$. The compression can proceed no farther, and the two bodies must now proceed in contact with this velocity.

And thus we see, that in the case of compressible, but unelastic bodies, the changes of motion are produced by the cohelive forces inherent in the bodies; but not inherent in them because they are in motion. We fee clearly in this way, how the pendulum used by Robins and his followers gave a true measure of the velocity of the ball. All the while that it was penetrating into the pendulum, overcoming the collesion as it went in, this cohesion was acting equally in both directions. While the fibre was breaking, it was pulling both ways; it was holding back the ball which was breaking it, and it was pulling forward the parts to which it still adhered; and when it broke at last, it had produced equal effects on the ball and on the pendulum in opposite directions. By such a process, the pendulum was gradually accelerated, and acquired its utmost velocity when the ball had ceased to penetrate:

Therefore, this velocity must be = $\frac{1}{A + pend^m}$. What should we now expect to happen in the col-

lision of bodies? Such bodies as exhibit perfect e-

lasticity, when examined by bending, or other sit trials, should have their motions changed precisely like the magnets, or bodies which repel or avoid each other at sensible distances. Bodies which exhibit no elastacity whatever, should continue in contact after The common velocity in these should be A = B b. The perfectly elastic bodies should sustain changes of motion which are precifely double of the changes fustained by unelastic bodies, and should separate after collision with a relative velocity of recess or feparation, precifely equal to their relative velocity of mutual approach. And bodies possessing imperfect elaflicity, should fustain changes of motion, which differ from the changes on unelastic bodies, precifely in proportion to the degree of elasticity which they are known to possess. And, lastly, if the changes of motion which obtain in the collision of bodies, are precisely those which would refult from the operation of those inherent

forces of elasticity and cohesion, no other force

WHATEVER CONCURS IN THEIR PRODUCTION: For

we know that those forces do operate in the collision; Impulsion. we see the compression and restitution which are their effective causes, and their immediate effects. If any other force were superadded, we should see its essects also, and the motions would be different from what they

Now the fact is, that we have never feen a body that is not, in some degree, compressible. It has not pleased the Almighty Creator to make any fuch here below. Affuredly He has not found such to be of use for the purpotes He had in view in this our fublunary world. We know of no body that is perfectly unchangeable in its shape and dimensions. It is therefore no loss whatever to us, although we should not be able to fay à priori what their motions will be in collision. We cannot even fairly guess them, by reasoning from what we obferve in other bodies: For it is just as likely that their motions may resemble those of perfectly elastic bodies as those of unelastic bodies; for we find that bodies of the most extreme hardness are generally highly elastic. Diamond, crystal, agate, quartz, and such like, are the most elastic bodies we know. Philosophers, however, rather think that the motions of perfectly hard bodies will refemble those of unelastic bodies; because elasticity supposes compression. We do not pretend to say with confidence, what would be the motion of a fingle atom of matter (which cannot admit of compression). which is hit by another in motion. We fee all the particles of terrestrial matter connected with each other by certain modifications of the general force of cohesion, so as to produce various forms of aggregation; such as aërial fluidity, liquid fluidity, rigidity, foftness, ductility, firmness or hardness; all of which are combined with more or less elasticity. These tangible forms refult from certain positive properties of the material atoms of which the particles are composed; and, in all the cases which come under our observation, these properties produce pressures of one kind or another; all of which are moving forces. They are inherent in the particles and atoms: therefore when fuch atoms are in motion, these forces are in a condition which affords occasion for a continuation of this pressure that is competent to the production of motion in another particle. But what would be the event of the meeting of atoms divested of such forces, we profess not to know, or even to conceive.

The fact also is, that all the changes of motion, com The obsermonly called impulsions, which have been observed, are ved effects precisely such as have been described. Unelastic bodies of collision

proceed in contact with the velocity $\frac{Aa \pm Bb}{A + B}$. are perfect-Per-ly conformable to the fectly elastic bodies separate after collision, and each proposifustains double of the change that is sustained by an untions now elastic body. Bodies of imperfect elasticity differ from the two fimple cases, precisely in the proportion of the elasticity discoverable by other trials. The mutual actions are observed to be in the proportion of their relative motions, whatever the real motions may be. For

not only are the changes of progressive motion exactly in this proportion, but the compressions and changes of figure, which we confider as the immediate occasions of those actions, are also observed to be in the same proportions, in all cases that we can observe and measure with

great precision by means of the collision of pendulous bodies in the way pointed out by Sir Christopher Wren (a method attributed by the French to their country. man Mariotte, but really invented by Wren, and exhibited to the Royal Society of London the week after he communicated his theory of impulsion).

We must also infer from these facts, that the actions

proof of the of bodies on each other are mutual, equal, and opposite. univerfality This is really an inference from the phenomena, and of equal actuot an original or first principle of reasoning. The tion and re-contrary is conceivable, and therefore not absurd. the fame way that we can conceive a magnet repelling iron, without imagining that the iron repels the magnet, we may conceive a golden ball capable of impelling a leaden ball before it, without conceiving that the leaden ball will impel the golden ball. We do not find this eafy indeed; because the contrary is so familiar, that the one idea instantly brings the other along with it. We apprehend it to be impossible to demonstrate, that a leaden ball will not stop as foon as it hits the golden ball, or vice versa. But all our experience shews us, that the pressures exerted in contact are mutual, equal, and opposite. The fame thing is observed in the forces which connect the parts of bodies. A quantity of fand or water balanced in a scale will remain in equilibrio in whatever way it is flirred about; its parts always exert the same pressure on the scale: so does a body suspended by a thring or refting on the scale, by whatever points it is supported. This could not be if the particles did not exert mutual and equal forces; nor could the phenomena called impulsions be what they are, if the pressures occasioned between the particles by the compressions and dilatations were not mutual and equal. This law of action and reaction must be admitted as universal, though contingent, like gravity. Doubtless it results from the properties which it has pleased the great Artist to give to the matter of which He has formed this world. There is one way in which we can conceive, most distinctly, how this may be a universal property of matter. If we grant the reality of attractions and repulsions e distanti, and suppose that every primary atom of matter is precifely similar to every other atom in all its properties, and that this affemblage of properties constitutes it a material atom; it follows, that every atom exerts the fame attractions and repulsions, or has the same uniting and evalive tendencies, and then the law of action and equal reaction follows of courfe. This is furely the very notion that any person is disposed to entertain of the matter. And if mechanical force and mobility are the qualities which diffinguish what is material from mind or other immaterial Substances, the law of equal and contrary reaction seems nearly allied to the class of first principles.

Of all the phenomena that indicate this perfect equality of action and reaction, the most susceptible of accurate examination is the fameness or equality of action" when the relative motions are equal. Now there is no phenomenon more certain than this. In consequence of the rotation of the earth round its axis, and its revolution round the fun, it is plain that all our experiments and observations are on relative motions only. Now, we not only find that the actions of two bodies subjeced to experiment are equal when the relative motions

Impulsion. accuracy. All these things can be ascertained with are equal, but we find that all our measures of action Impulsion. on a fingle body are proportional to the apparent motions which they produce. It requires precifely the fame force to impel a ball eastward, westward, fouth, or north, at 12, or 3, or 6, or 9 o'clock: yet the real motions are immenfely different in all these cases, and it is only the relative motions that have the proportions which we observe. Another very important point deducible from our experiments is, that the same pressure produces the same change of motion, whatever may be the velocity. We know this by observing, that when the mutual dimpling or compression is the same, the change of motion is the fame, whatever be the hour of the day. This could not be if it required a greater pressure to change the velocity 100000 into 100001, than to change the velocity 1 into the velocity 2. Yet this is one of Leibnitz's great metaphyfical arguments for proving that the force accumulated, and now inherent, in a moving body, is proportional to the square of its velocity. We beg that this may be kept in remem-

It must be granted, that what we have already said on the subject of impulsion may be called an explanation; for it deduces the phenomena from general and unquestionable principles, and from acknowledged laws of Nature. The only principle used is, that a moving force is indicated, characterised, and measured, by the motion which it produces. It is an acknowledged law of Nature, that pressures are moving forces; also, that moving forces appear in cases where we observe neither pressures nor impulsions, and which we call repulsions or evalive tendencies; that these are mutual and equal: and we have shewn, how a certain set of changes of motion refult from them, and have flated diffinctly the whole process: we shewed, that these phenomena are similar to those of common impulsion; and we then shewed in what manner the motion of a body gives occasion to the exertion of various moving forces, called elasticity, cohesion, &c. and that this exertion must produce motions fimilar to those produced by repultions e distanti; and, lastly, we inferred, from the perfect fameness of those results with the actual phenomena of impulsion, that those corpuscular forces are the immediate and only causes of the changes called impulsions, and commonly afcribed to a peculiar force inherent in a moving body.

From a collective view of the whole, we think it clear, 49 Why does that the opinion that impulsion is the fole cause of mo- why mes tion is unwarranted. We fee that the phenomena of pher attempt impulsion are brought about by the immediate operation o explain of preffure; and we fee numberless instances of preffure, gravitation, in which we cannot find the fmallest trace of impulsion. ecc. by mi It is therefore a most violent and unwarranted opinion, which afcribes to repeated unperceived impulsions all those folicitations to motion by which, or in consequence of which, the motions of bodies are affected by distant bodies, or bear an evident relation to the situation and diftance of other bodies; as in the examples of planetary deflection, terrefirial gravitation, magnetical and electrical deflexions, and the like. There is nothing in the phenomenon of the pressure of gravity that seems to make impulsion more necessary or more probable than in the pressure of elasticity, whether that of a spring or of an expansive fluid. The admission of an unpercei-

In lion ved fluid to effect those impulsions is quite unwarranted, and the explanation is therefore unphilosophical, even although we should perceive intuitively that an atom in motion will put another into motion by hitting it. We apprehend that this cannot be affirmed with

any clear perception of its truth.

On the whole, therefore, we must ascribe that conis posed tented acquiescence in the explanations of gravitation, and other attractions and repullions, by means of impulse (if the acquiescence be not pretended), to the frequercy and familiarity of impulsion, and perhaps to the personal share and interest we have in this mode of producing motion. We know that it is always objected that nothing is explained, when we fay that A repels B, or that B avoids A; but we must fay in return, that nothing is explained, when we fay that A impels B by hitting it, or that B flies away from the stroke. Why should it not be allowed to use the term repelling power, when it is allowed to use the term impelling power, the force of impulse, inertia? All these terms only express phenomena. Does the word body express

51 not

ter un-

flood.

at more

fa liar.

The maxim, that a body cannot act where it is not, any more than when it is not, is a quaint and lively expression, and therefore has considerable effect: It may be granted; for we apprehend that we understand so little about when and where, that we cannot demonstrate the affirmative or negative in either case, and that they are on a par with respect to our knowledge of them. We can have no doubt, however, of the fact, that our mind can be affected by an external object that is merely recollected. And we apprehend, that we know nothing of the difference between body and mind but what we have learned by experience. Body, for any thing that we affuredly know to the contrary, may affect, or be affected by, a distant body, as well as mind may be. It is therefore worth while to pay fome farther attention to the phenomena, in order to see whether this experience is fo univerfal and unexcepted as is believed. As Mr Cotes, and many of Newton's disciples, are accused of explaining many phenomena by attraction and repulfion which their opponents affirm to be cases of impulfion; it is not impossible but that ordinary observers, who have no preconceived theories, may imagine impulfions to obtain in cafes where a more accurate inspection would convince them that no impulsion has happened. When we kick away a foot-ball, we confider it as

nquiry in-

othefami a fort of folid continuous body; yet we know that arity of it must be filled with compressed air. It may not offines of be impossible to have it of its round shape without befoot-ball. ing fo filled: but we know that, in this condition, it would not fly away from our foot by the stroke; we should only force in the fide which we kick, and the flaccid skin would lie at our feet. But when it is silled with strongly compressed air, we can form to ourfelves a pretty distinct notion how it is made to move off. Our foot presses on a part of the skin: this compresses the air against the anterior part of the bag, and forces it away. If we reflect more feriously on the process, we can still conceive it clearly enough, by thinking on a row of aereal particles, reaching from the part struck by the foot to the anterior part, each touching the other, and therefore forcing the anterior part forward. The air is conceived to confift of a number Suppl. Vol. I. Part II.

of little spherules in contact, each of which is com- Impulsion. pressible; and we think the operation illustrated by fuppoling each to be like a little vehicle or bladder. This we believe to be the usual way of conceiving the conflitution of expansive fluids: But this will not agree at all with the known properties of air; for it can be strictly demonstrated, that if such a collection of elastic vesicles be compressed into the half of their ordinary bulk, every vehicle will be changed from a sphere into a perfect cube, touching the adjoining cubes in every point of its fix fides, and strongly pressed against them. It can also be demonstrated, that if a leaden cube of one inch be included in the box, and placed with its fides parallel to the fides of the box, and the compreffion be then made, all the little cubic veficles will acquire the same position. If the box be now turned upfide-down, it can be demonstrated that the weight of this leaden cube will not be fufficient for overcoming the refistance of the compressed cubes. This compresfed mass will not be fluid, but will require a very confiderable force to prefs the leaden cube through it, just as we find fuch a force necessary for moving a body through melted glass: the particles no longer slide on each other like uncompressed foherules; each will require about half of the compressing force, in order to overcome the friction, or ob! ruction like friction, produced in sliding along the furface of the contiguous cubes. But we know that air remains perfectly fluid, although vastly more compressed than this. This, therefore, cannot be like the constitution or form of air. Moreover, it is well known that air has been made ten times denfer than its ordinary flate, and is then perfectly fluid. It has also been made a hundred times rarer, and it still remains perfectly fluid. In this state its particles must be ten times farther removed from each other than in the former state, of a thousand times greater density. Yet we know that this rare air is compressed with a force equal to the weight of a stratum of mercury 1 d of an inch in thickness, and that if id of this pressure be removed, it will expand till it is 150 times rarer than common air; that is, there is fome force which pullies the particles still farther from each other. This force evidently extends beyond the tenth particle of air that is made ten times denser than common air. Therefore the elasticity of air does not arise from the contact of particles, which are elaftic like blown up bladders, but from some force which extends beyond the adjoining particles. There is no greater reason, therefore, for supposing, that the particles of air touch each other, than for supposing that the two magnets touch each other because they repel. A row of magnets floating on quickfilver, and placed with their fimilar poles fronting each other, and very near, will tend to feparate, and they require to be held in by a stop put at each end of the canal; and if one stop be gradually withdrawn, the magnets will all feparate, and exhibit the general mechanical effects of a row of aereal particles separating by the removal of pressure. There seems, therefore, to be the fame necessity for the operation of an intervening impelling fluid for producing this feparation or clafficity of the aereal mass, as for separating the magnets.

The result of these remarks seems to be, that the Is very impulsion of a foot-ball is not brought about in the doubtful. way that is commonly imagined, by the excitement of

Impulsion. corporeal pressure at the points of contact of the two when one glass carries the other, without any appear. Impulsion, foot-balls. For we fee it almost demonstrated, that the progressive motion of the anterior part of one of the balls has been produced without contact, or, at least, by the intervention of repulsions acting at a distance.-May not this obtain, even in the points in which we suppose the two balls actually to touch, in the act of impulsion?

Many cafes of doubtful contact.

But farther—Every person has observed the brilliant dew drops lying on the leaves of plants. Every person acquainted with Newton's optical discoveries, must be convinced that the dew-drop is not in mathematical contact with the leaf; if it were, it could have no bril. liancy. Most persons have observed the rain drops of a fummer shower fall on the surface of water, and roll about for a few feconds, exhibiting the greatest brilliancy. They cannot, therefore, be in mathematical contact with the water. There must be a small distance between them, and therefore some force which keeps them afunder, and carries the weight, that is, counteracts the downward pressure of the rain drop. We know that fome infects with long legs can run about on the furface of water; and if we lift them carefully, and fet them on glass, their feet do not wet it. Put a little spirit of wine into this water, and make it lukewarm, and the infect inftantly finks up to the belly, and cannot move about as before: Its feet will now wet a glass. A well-polished steel needle, even of confiderable fize, if perfectly clean and dry, will float on water without being wetted: It is observed to make a confiderable depression on the surface of the water, just as a heavy bar of iron would make when laid on a feather bed - the needle displaces a quantity of water equal to itself in weight, yet does not touch it, for it is not wetted. If it be previously wetted, it will not displace any water, and will not float. There is something, therefore, which keeps the water at a diffance from the feet of the infect, and from the needle, exerting a certain upward pressure on them. The pressure and the reaction are indeed very small; but they would produce a very fensible motion if continued sufficiently long in proper circumstances. Here would be a production of motion, which most persons would call an impulsion - yet there would be no stroke, no contact, and therefore no true impulsion.

We now beg the reader to attend minutely to Newton's famous experiment with the object glaffes of long telescopes, which we have mentioned circumstantially

in the article Optics, Encycl. nº 63-68.

When the upper glass is very thin and light, no colour appears at the point of contact: but by prefease of con- fing it down with sufficient force, we shall have a black or unreflecting spot in the middle, surrounded by a fil. feeming to very ring, and then by a feries of rings of various colours, according to the distance between the parts of the glasses where the colours appear. Newton has counted 50 of these rings. He shews, by a careful computation from the known figure of the glaffes, that the differences between the distances which exhibit these colours are all precisely equal, and that each is about $\frac{1}{8900}$ of an inch. Therefore, supposing that the glasses are in mathematical contact where the unrestecting fpot appears, making one continuous mass of glass, their distance at the outermost ring must not be less than 5000 of an inch, or 180 of an inch. Therefore, ite pair of lenses, we broke the uppermost by too

ance of colour at the middle, we must conclude that there is a repulsion exerted between the nearest parts, at a distance not less than 1 of an inch, sufficient for supporting the upper glass. It requires an increase of pressure to produce the first appearance of colour; and when the pressure is still more increased, new colours appear in the middle, and the colour formerly there is now feen in a furrounding ring; these multiply continually, by new ones fpreading from a central spot. A great pressure at last produces the unreslecting fpot in the centre, which, unlike to all the coloured fpots which had emerged in fuccession, is sharply defined, and never round, but ragged, and it is immediately furrounded by a bright filvery reflection. The shape of this spot depends on the figure of the furfaces; for, on turning the upper lens a little round its axis, the inequalities of the edge of the fpot turn, in fome degree, with it. This feemingly trifling remark will be found important by the mechanician: A still farther increase of pressure enlarges the unrestecting fpot, and the dimensions of all the rings-When the pressure is gradually withdrawn, the rings shrink in their dimensions, the unreflecting spot disappears first, and each ring in fuccession contracts into a spot, and vanishes. Here we have, by the way, an explanation of the brilliancy of dew drops: they come fo near, per-

haps, that the nearest point reflects the silvery appearance - but they do not touch; the instant that they touch a wetted part, making one mass of transparent matter, all brilliancy is gone. Here then are incontestible proofs of a force, be its They repel origin what it may, which keeps the glaffes afunder, each other; and even causes them to separate; which manifests itfelf by withstanding pressure; and therefore is, itself, a

pressure, or equivalent to a pressure-It varies in its intensity by a change of distance; but we have not been able to afcertain by what law. It must not be meafured by the simple variation of the external pressure; for fince we fee that, even before any colour appears in the centre, the weight of the upper lens is supported, we must conclude that the glasses are exerting at least an equal force all around the circumference of the outermost ring. It is evident, that the computation of the whole force, exerted over all the coloured surface, must be difficult, even on the simplest hypothesis concerning the law of repulsion: we can only fay that it increases by a diminution of distance. It is very easy to compute the increase of external pressure, which would fuffice if the repelling force were equal at all distances; or if it varied according to any single power of the distances. We have tried the inverse simple, duplicate, and triplicate ratio; but the fact deviated widely from them all. The repulfion does not change nearly fo much as in the simple inverse ratio of the distances, if the glasses be supposed to touch in the whole furface of the unreflecting spot. But we found, that if we suppose them separated, though at a distance equal to forty times the difference of distance at which the colours change, that is, z z of an inch, the preffures employed in the experiment accord pretty well with a repulsion inversely as the distance, but still with a very confiderable deviation in the great pressures. In the course of a number of experiments with a favour-

Very re markable vex lenfes spullion. firong a pressure. We then cut out of it, with a lapidary's hollow drill, a piece of 1 of an inch in diameter, and perfectly round, and we squeezed it on the other by a measured pressure, till we produced a colourless spot of nearly th of an inch in diameter, with a filvery margin. Computing from this, we thought ourselves warranted to say, that not less than 800 pounds are necessary for producing a black spot of one inch

36 nd may

Now, what is the consequence of all this in the docopel with trine of impulsion? Surely this: - If a lump of this glass strike another lump, and put it in motion, and if the mutual pressure in the act of collision do not exceed 700 pounds on the square inch, the motion has been produced without mathematical contact, and the production can no more be called impulse than the motion of the magnet in our first experiment. The changes of motion have been the operation of moving forces, similar to the force of magnetism; and if a stream of truly impelling fluid be necessary for producing the motion of the magnet, it is equally necesfary for producing the motion of the piece of glass.

It may be faid here, that we cannot compare impulse and preffure. A flight blow will fplit a diamond which could support a house. A slight blow may therefore be enough for exciting all the pressure necessary for producing mathematical contact. We must here appeal to what every man feels on this occasion. We doubt exceedingly whether any perfon will think that, when one piece of glass gives another a gentle blow, and puts it into motion, with the velocity of a few inches per fecond, a blow which he distinctly hears, there has been exerted a preffure at all approaching to 800 pounds per square inch. - We have suspended a pair of lenses, Ly an opparatus fo fleady and firm, that they could touch only at the centres of each furface; and, having placed ourselves properly, we could see, with fufficient diffinctness, the momentary appearance of the coloured spot at the instant of collision. We faw this, with the fullest confidence that it was of no considerable breadth in a moderate stroke, and that it was very fenfibly broader when the stroke was more violent. We did not trust our own eye alone, but shewed it to perfons ignorant of philosophy, and even to children, often without telling them what to look for, but asking them what they faw. From all the information that we could gather, none of the preffures came near to what must have been necessary for producing the black spot. This could not be mittaken: for although the outer rings are but faint, there are five or fix near the centre which are abundantly vivid for affecting the eye by the momentary flash. Besides, the dimensions of the lenses, and the weight of the metal cells in which they were fixed, were fuch as must have caused them to split before the black fpot could be produced in the centre.

These things being maturely considered, we imagine that few persons will now doubt the justice of our afso, even in fertion, that in all these examples, the motions have been produced without mathematical (or rather geometrical) contact. - And we imagine also, that few will refuse granting that this is not peculiar to glass, but obtains also in the collision of other bodies. We have not thought of any method for putting this beyond doubt; but we have better reasons than mere likelihood for being of this opinion. Every one acquainted with the

Newtonian discoveries in optics, knows that this cu. Impulsion. rious appearance of the coloured rings is the confequence of the action of transparent bodies on the rays of light, by which these are bent aside from their rectilineal course, and that this deflection takes place at a distance from the diaphanous body; a distance which the fagacity of the great philosopher has enabled us to measure. Now, it is known that metals and other opake bodies produce the very fame deflections of the rays, bending them toward themselves at one distance, and from them at other distances; in short, attracting or repelling them as the diffance varies. Nothing but prepoffession can hinder a person from ascribing similar effects to fimilar causes; and, therefore, thinking it almost certain, that this mutual repulsion is not peculiar to glass, but common to all solid bodies.

To all this we may furely add the celebrated experiment of Mr Huyghens; in which it is evident, that a fmooth plate of metal attracts another, even although there be a filk fibre interposed between them. (See Phil. Tranf. n° 86). Is it not highly probable, that at a smaller distance the bodies repel each other? For we observe, that metals, as well as transparent bodies, attract the rays at one distance and repel them at

Surely our readers will now grant, that the produc-impulsion tion of motion by impulfion, as diftinguished from theis not fo faproduction by action e diffanti, is not so familiar a phe miliar as is nomenon as was imagined, and that it may even be faid to be rare in comparison: for the instances of moderate impulses are numberless. The claim of this mode of explaining difficult phenomena by impulsion, has therefore lost much of its force; and we see much less reason for calling in the aid of invisible fluids, in order to explain the action of gravity, magnetism, and electri-

But we have still more important information from Still greater the optical discovery of Newton. Let the reader turn lo bt Obagain to Optics, Encycl. n 65, and read the account fervations of the phenomena exhibited by the foap-bubble. The bubble. bubble is thinner and thinner as we approach the very uppermost point of it. It also exhibits luminous rings, which vary in their colour, in the same order as in the fpace between the lenfes. These rings come to view in the fame manner. First, a coloured spot appears in the fummit of the bubble; this becomes a ring, and is succeeded by another spot, as the bubble grows thinner in that part, by the gradual fubliding of the watery film. At last a black spot appears at top, well defined, but of irregular shape, surrounded by a filvery ring. This fpot, when viewed very narrowly, is obferved to reflect a very minute portion of light, without feparating the differently colorific rays of which it confifts; but it contains them all, as may be proved by viewing it through a prism. After some little time,

the bubble bursts. Surely we must infer from this, that there is a certain thickness of the transparent plate which renders it unfit for the vivid reflection of light. Does it not legitimately follow from this, that the unreflecting spot between the lenses ceases to entitle us to fay, that they are in contact in that place? All that we can conclude from its appearance is, that the distance still between the glasses is too small to fit the place for the vivid reflexion of light. This conclusion is indisputable. Were

5 I 2

Impulsion, it refused, we are furnished with an incontestible proof by the same bountiful hand. Newton ascribed the colours to the reflection of the plate of air between the glasses, and expected the cestation of them when the air is removed. His friend Mr Boyle had lately invented a commodious air pump. The trial was made, and young Newton found himself mistaken; for the colours flill appeared, and he even thought them more brilliant. He then tried the effect of water, expecting that this would diminish their lustre. So it did; and he found that the dimentions of the rings were diminished in the proportion of 4 to 3; namely, the proportion of the refractions of glass and water. By this time Newton had discovered the curious mechanical relation between bodies and the rays of light; and his mind was wholly absorbed by the discovery, and by the revolution he was about to make in the mathematical doctrines of optics. Unfortunately for us, he did not, at that time, attend to the mighty influence which the difeovery would have on the whole of mechanical philosophy, and therefore occupied himfelf only with fuch phenomena as fuited his present purpose. A most important phenomenon passed unnoticed. In repeating Sir Isaac Newton's experiments, we found that the diameters of the rings decreased in the proportion of 4 to 3 only in certain circumstances. When the upper lense was pressed on the other by a heavy metal ring, so as to produce three or four coloured rings, we found, that when water got between them, fometimes no colours whatever appeared; fometimes there was a ring or two, and the diameters were diminished in a much greater proportion than Newton had affigned. Well affured of the extreme nicety of all his proceedings, we were much puzzled with this difcrepancy, and mentioned it to a most respectable and intelligent friend, the late Dr Reid of the university of Glasgow, a mathematician and naturalist of the first rank. He thought it not improbable that the glasses separated from each other, lifting up the weight, by attracting the water into the interstice, in the same manner that we observe wood to fwell with moisture. We immediately got an apparatus which compressed the glasses by means of four screws; and now we faw Newton's proportion most strictly obferved. But in profecuting the experiment, we found that the introduction of the water always effaced a very fmall fpot. This happened after precautions had been taken to prevent all feparation of the glaffes. As the proportion of 4 to 3 has a relation to refractive power, although we have not been able to deduce it as a necessary consequence, we nevertheless considered it as a sufficient proof, that the distance of the glasses bad not changed by introducing the water between them. Therefore we think ourfelves well entitled to conclude, that the disappearance of the black spot was not owing to a separation of the glasses, which admits the water into the empty space; and we affirm, that before the entry of the water, there was room for it in the place which reflected no light; that is, that although the glaffes were pressed together with a very great force, they were not in contact.

It deferves remark, that in endeavouring to produce the black fpot, when water is between the glaffes, we found great and unaccountable anomalies. Sometimes a moderate increase of pressure produced it, and sometimes we were not able to produce it by any pressure.

Several lenses were broken in the trial. We are led to Impulsion. think that the thickness which gives the filvery reflection is much greater than the 8900th part of an inch, and that it is not the fame in all glaffes. But we were interrupted in these experiments, and indeed in all active purfuits, by bad health, which has never permitted their renewal. The subject is of great importance to the curious mechanicians, and we earneftly recommend it to their attention. There is fomething very remarkable in the abrupt cellation of the coloured reflection. At a certain thickness all colours are reflected, without separation, producing the whiteness of silver. The smalleft diminution of it hinders the vivid reflection of all colours, and then there feems to fueeeed a thickness which equally reflects a fmall proportion of all without separation. The finest polish that can be given to glass in the tool of the artist, leaves irregularities which oe. casion the irregular ragged figure of the spot. It is worth trying, whether finoothing the furfaces (both) by a foftening heat will remove this ruggedness. If it does, without destroying the sharp termination, it will prove the abrupt passage from esse to nonesse.

The last remark to be made on this important experiment in optics is, that the distance between the glaffes which is unfit for vivid reflection, eannot be determined by means of the other measurable intervals. It may be equal to many of them taken together. The same must be granted with respect to the thickness of the black fpot on the top of the foap bubble. We attempted to measure this thickness by letting a drop (of a known weight) of spirit of turpentine spread on the surface of water. As it flowly enlarged in furface, it decreased in thickness, and produced, in regular order, several of the more compounded colours of the Newtonian feries. But before it came to the 20th ring from the centre, it Lecame very irregular and fpotty.

The inference to be drawn from this combination of Contact is the two optical facts is remarkable and important. It not proved is, that we have no authority for affirming that the changes of motion by the collision of bodies is brought about by absolute contact in any instance whatever. The glasses are not in contact where there is vivid reflection; and we have no proof that they are in contact in the black spot, however great the compression may

It is hardly necessary now to fay, that all attempts therefore to explain gravitation, or magnetism, or electricity, or impulsion any fuch apparent action at a diffance by the impulsions cannot exof an unfecn fluid, are futile in the greatest degree. plain gravi-Impulsion, by absolute contact, is so far from being a familiar phenomenon, that it may justly be questioned whether we have ever observed a single instance of it. The supposition of an invisible impelling fluid is not more gratuitous than it is useless; because we have no proof that a particle of this fluid does or can come into contact with the body which we suppose impelled by it, and therefore it can give no explanation of an action that is apparently e distanti.

The general inference from the whole feeins to be, But impulthat, instead of explaining pressure by impulse, we must sion may be not only derive all impulie from preffure, but must also explained ascribe all preffure to action from a distance of the contiascribe all pressure to action from a distance; that is, nued presto properties of matter by which its particles are moved fure. without geometrical contact.

This collection of facts conspires, with many appear-

pulsion. ances of fluid and folid bodies, to prove that even the particles of folid, or fenfibly continuous bodies, are not in contact, but are held in their respective situations by the balance of forces which we are accustomed to call attractions and repullions. The fluidity of water under very strong compressions (which have been known to compress it 10 of its bulk), is as inconsistent with the fupposition of contact as the fluidity of air is. The shrinking of a body in all its dimensions by cold, nay, even the bending of any body, cannot be conceived without allowing that fome of its ultimate unalterable atoms change their distances from each other. The phenomena of capillary attraction are also inexplicable, without admitting that particles act on others at a distance from them. The formation of water into drops, the coalescence of oil under water into spherical drops, or into circular spots when on the furface, shew the same thing, and are inexplicable by mere adhesion. In short, all the appearances and mutual actions of tangible matter concur in shewing, that the atoms of matter are endowed with inherent forces, which cause them to approach or to avoid each other. The opinion of Boscovich feems to be well founded; namely, that at all fenfible diffances, the atoms of matter tend toward each other with forces inverfely as the squares of the diffances, and that, in the nearest approach, they avoid each other with insuperable force; and, in the intermediate distance's, they approach or avoid each other with forces varying and alternating by every change of distance. See the article Boscovich, Suppl.

hyfical lained.

From all that has been faid, we learn that physical ontact ex- or fensible contact differs from geometrical contact, in the same manner as physical solidity differs from that of the mathematician. Euclid speaks of cones and cylinders standing on the fame bafe, and between the fame parallels. These are not material solids, one of which would prefs the other out of its place. Physical contact is indicated, immediately and directly, by our fense of touch; that is, by exciting a pressure on our organ of touch when it is brought fufficiently near. It is also indicated by impulsion; which is the immediate essent of the pressure occasioned by a sufficient approximation of the body impelling to the body impelled. The impulfion is the completion of the fame process that we defcribed in the example of the magnets; but the extent of space and of time in which it is completed is so small that it escapes our observation, and we imagine it to be by contact and in an inftant. We now fee that it is fimilar to all other operations of accelerating or retarding forces, and that no change of velocity is inftantaneous; but, as a body, in passing from one point of space to another, passes through the intermediate space; fo, in changing from one velocity to another, it passes through all the intermediate degrees without the smallest saltus.

And, in this way, is the whole doctrine of impulsion avoid mary brought within the pale of dynamics, without the adabfurdities mission of any new principle of motion. It is merely the application of the general doctrines of dynamics to cases where every accelerating or retarding force is oppofed by another that is equal and contrary. We have found, that the opinion, that there is inherent in a moving body a peculiar force, by which it perfeveres in motion, and puts another in motion by shifting into it,

is as useless as it is inconfishent with our notions of mo- Impulsion. tion and of moving forces. The impelled body is moved by the infuperable repulsion exerted by all atoms of matter when brought fufficiently near. The retardation of the impelling body does not arife from an inertia, or refilting fluggishness of the body impelled, but because this body also repels any thing that is brought sufficiently near to it. We can have no doubt of the existence of fuch causes of motion. Springs, expansive fluids, cohering fibres, exhibit fuch active powers, without our being able to give them any other origin than the FIAT of the Almighty, or to comprehend, in any manner whatever, how they refide in the material atom. But once we admit their existence and agency, every thing else is deduced in the most simple manner imaginable, without involving us in any thing incomprehenfible, or having any confequence that is inconfident with the appearances. Whereas both of these obstructions to knowledge come in our way, when we suppose any thing analogous to force inherent in a moving body folely because it is in motion. It forces us to use the unmeaning language of force and motion passing out of one body into another; and to speak of force and velocity as things capable of division and actual separation into parts. The force of inertia is one of the bitter fruits of this misconception of things. It is amusing to fee how metaphylicians of eminence, such as D'Alembert, endeavour to make its operations tally with acknowledged principles. In his celebrated work on dynamics, the most elaborate of all his performances, he explains how a body, whose mass is 1, moving with the velocity 2, must stop another body whose mass is 2, moving with the velocity 1, in the following manner: He supposes the velocity 2 to consist of two parts, and that, in the instant of collision, one of these parts destroys the motion of one half of the other body, and then the other part destroys the motion of the other half. These are words; but in vain shall we attempt to accompany them by clear conceptions. His diffinction between the force of inertia and what he calls the active forces of bodies, fuch as the force of bodies which strike each other in opposite directions, is equally unsusceptible of clear conceptions. Active forces (says lie) abforb a part of the motion; but when inertia takes part of the motion from the flriking body, this motion passes wholly into the body that is stricken, none of it being absorbed or really destroyed. He demonstrates this by the equation $A \times a - x = B \times x - l$, which is a mere narration of facts, but no deduction from the nature of inertia, nor even any establishment of that nature by philosophical argument. And in attempting to give still clearer notions (being fensible that some great obfcurity still hangs about it), he says, " Inertia therefore, and properly speaking, is the mean of communicating motion from one body to another. Every body refifts motion; and it is by refifting that it receives it; and it receives precifely as much as it destroys in the body which acts on it." Surely almost every word of this sentence is doing violence to the common use of language. What can be more incomprehensible than that a body refifts motion only when it receives it? Should a man be thought to refift being pushed out of his place when he actually allows another to displace him, and not to refift when he firmly keeps his place? All these difficulties and puzzling questions vanish when

Impulsion, we give over speaking of inertia as something diffinguishable from the active forces or causes of motion which we find in bodies, and distinguish by the names of elasticity, cohesion, magnetism, electricity, weight, &c. and which philosophers have classed under one name, accelerating or retarding force, according as its direction chances to be the fame, or the opposite to that of the motion under confideration. To suppose it a peculiar faculty by which a body maintains its condition of motion or rest, is contrary to every conception that we can annex to the words faculty, power, force. is frivolous in the extreme to fay, that fnow has the faculty of continuing white or cold; or that it refifts being melted because it melts, or because heat must be employed to melt it.

Strongeft argument for inertia is the com-

The only argument that we know for giving the name force to the perseverance of matter in its state of motion (or rather for ascribing this perseverance to the exertion of a peculiar faculty), which appears to deforce with ferve any attention, is one that we do not recollect the express employment of for this purpose, namely, the composition of a previous motion with the motion which a known force would produce in the body at rest. We know, that if a body be moving eastward at the rate of four feet per fecond, and a force act on it which would impel it from a state of rest at the rate of three feet per fecond to the fouth, the body will move at the rate of five feet per second in the direction E. 36° 52' S. We know also, that if a force act on this body at rest, fo as to give it a motion eastward at the rate of four feet per second, and if another force act on it at the fame instant, so as to give it a motion to the south at the rate of three feet per second, the body will move at the rate of five feet per second in the direction E. 360 52' S. In this instance, the body previously in motion feems to possess fomething equivalent to what is allowed to be a moving force. Why therefore refuse it the name? The auswer is easy. The term force has been applied, by all parties, to whatever produces a change of motion, and is measured by the change which accompanies its exertion. There is some difference between the parties about the way of estimating this measure; but all agree in making, not the motion, but the change Answered, of motion, the basis of the measurement. Now we shewed, at great length, in the article Dynamics, that the change of motion, in every case, is that motion which, when compounded with the former motion, constitutes the new motion. Did we take the new motion itself as the characteristic and measure of the changing force, it would be different in every different previous state of the body, and would neither agree with our general notion of force, nor with the knowledge that we have of the actual pressures and other moving forces that we know. The fole reason why the previous motion is equivalent with a force is, that the only mark or knowledge that we have of a moving force is the motion which it is conceived to produce. The force is equivalent with the previous motion, because we know nothing of it but that motion; and the name that we give it, only marks fome external thing to which it has an observed relation. We call it magnetism or electricity, because we observe that a magnet or an electrified body gives occasion to its appearance. We never observe the refistance of inertia, except in cases where we know, from other circumstances, that moving

forces inherent in bodies are really brought into action, Impulsion, The inertia of the ball which has been moved by a stroke of another, is inferred from the diminution of that other's motion. But this is occasioned precisely in the same way as the diminution of the motion of the magnet A in the first example; an event which every unprepossessed person ascribes to the repulsion of B in the opposite direction, and not to its inertia.

We trust that our readers are not displeased with this detail of the procedure of Nature in the phenomena of impulsion. It has been prolix; because we apprehend, that the too synoptical manner in which the laws of collision have always been delivered, leaves the mind in great obscurity concerning the connection of the events. General facts have been taken for philosophical principles and elementary truths; whereas they were deductions from the fum total of our knowledge. They were very proper logical principles for a fynthetical discussion; but their previous establishment as general facts was necessary. We have established the two most general facts from which the result of every collifion may be deduced with the utmost ease. The first is, that in the instant of greatest compression, the com-

mon velocity is = $\frac{Aa = Bb}{A + B}$; and we have shewn, that this is applicable to the collision of unelastic bodies. The fecond is, that the change in perfectly elaftic bodies is double of the change in unelastic bodies. The conservatio momentorum, and the conservatio virium vivarum, are also general facts; or rather they are the fame mentioned with those above, considered in another aspect. They may all be used as the principles of a fynthetic treatife of impulsion; and they have been so employed. Each has its own advantages.

Mr Maupertnis gives a treatife on the Communica Principle tion of Motion, that is, of impulsion or collision, which it finalless has the appearance of being deduced from a new prin-action. ciple, which he calls the PRINCIPLE OF SMALLEST AC-TION. He supposes, that perfect wisdom will accomplish every thing by the smallest expenditure of action; and he chanced to observe, in the equations employed in the common doctrine of impulsion, a quantity which is always a minimum. He chooses to consider this as the expression of the action.

His principle or axiom, deduced from the perfect wisdom of God, is thus expressed: "When any change happens in nature, the quantity of action necessary for it is the smallest possible." And then he adds,

" In mechanical changes, the quantity of action is the product of the quantity of matter in the body by the space passed over, and by the velocity of the motion." This is evidently the measure adopted long before by Leibnitz (see Phil. Trans. vol. xliii. p. 423, &c.), and it is equivalent to $m v^2$; because the space multiplied by the velocity is as the square of either. We refer to Dr Jurin's remarks on this passage for proof that this is by no means a just measure of action; and only obferve here, that we can form no other notion of velocity than that of a certain space described in a given time. The change produced is not the actual description of a line, but the determination to that motion. It is in this respect alone that the condition of the body is changed; and therefore the product mv, and not msv, is the proper measure of the action. On the authority of this maxim of divine conduct, Maupertuis investi-

mum, and afferts that these must be the laws of collilion. Luckily this investigation is extremely simple, and very neat and perspicuous; and it gives very easy folutions. For example, the unelastic body A, moving with the velocity a, overtakes the unelastic body B, moving with the velocity b Both move after the collision with the velocity x. This velocity is required. To determine this, we must make $A \times a - x^2 + B \times a$ $|x-b|^2$ a minimum; or A a^2-2 A $ax+Ax^2+Bx^2$ - 2 Bbx + Bb2 is a minimum. Therefore - 2 Aax $+2 \text{ A} \times x + 2 \text{ B} \times x - 2 \text{ B} b \times = 0$, or 2 A a + 2 B b= $2 \text{ A} \times + 2 \text{ B} \times$, and $x = \frac{\text{A} a + \text{B} b}{\text{A} + \text{B}}$; as we have already shewn it to be.

The amiable and worthy author grew more fond of his theory, when he faw what he imagined to be its influence extended to an immense variety of the operations of nature. Euler demonstrated, that the quantity called action by Maupertuis was a minimum in the planetary motions, and indeed in all curvilineal mo-tions in free space. But all the while, this principle of least action is a mere whim, and the formula which is fo generally found a minimum has no perceptible connection with the quantity of action. In many cases to which Maupertuis has applied it, the conclufions are in direct opposition to any notion that we can form of the economy of action. Nay, it is very difputable whether it does not, on the contrary, express the greatest want of economy; namely, a minimum of effect from a given expenditure of power. In the case of impulsion, this minimum is the mathematical refult of the equality and opposition of action and reaction. Manpertuis might have pleased his fancy by saying, that it became the infinite wifdom of God to make every primary atom of matter alike; and this would have answered all his purpose.

There still remains to be considered a very material o the di-circumstance in the doctrine of impulsion, which produces certain modifications of the motions that are of mighty practical importance. We have contented ourfelves with merely stating the moving force that is brought into action in the points of physical contact; but have not explained how this produces the progreffive motion of every particle of the impelled body, and what motion it really does produce in the remote particles. A body, besides the general progressive motion which it receives from the blow, is commonly observed to acquire also a motion of rotation, by which it whirls round an axis. It has not been shewn, that when a body has received an impulse by a blow in a particular direction on one point, it will proceed in that direction, or in what direction it will proceed. Experience shews us, that this depends on circumstances not yet considered. The billiard player knows, that by a stroke in one direction he can make his antagonill's ball move in a

direction extremely different.

These are questions of great intricacy and difficulty, and would employ volumes to treat them properly. We have already enlarged this article till we fear that we have exhausted the reader's patience, and deviated from the proportion of room justly allowable to IMPUL-SION. We must therefore limit our attention to such things only as feem elementary, and indispensably ne-

ulfion gates the refults which will make this quantity a mini- ceffary for a uleful application of the doctrine of im- impulsion.

With respect to the direction of the motion produced by impulsion, the very example just now borrowed from billiard playing, shews that it is important, and by no means obvious. We are forry to fay, that we have nothing to offer in folution of this question that will be received by all as demonstration. It is comprehended in the following proposition, which we bring forward merely as a matter of fact.

The direction of the stroke or pressure exerted by Action of two bodies in phyfical contact, is always perpendicular bodies by to the touching furfaces. Of this truth we have a very contact is distinct and pretty example and proof by the billiard perpenditable. If two balls A and B (fig. 2.) are laid on the touching table in contact, and A is smartly struck by a third ball surface. C in any direction Cc, fo that the line aA, which joins the point of contact a with the centre A, may make an obtuse angle with the line AB, joining the centres of the two balls, the ball B will always fly off in the direction ABF. The preffure on B, which produces the impulsion, is evidently exerted at the point b of contact, and the direction BF is perpendicular to the plane G b H, touching both balls in the point b. The primary stroke is at a, and acts in the direction a A, although C moved in the direction Cc. Had A been alone, it would have gone off in the direction a A produced. But the force acting in the direction a A is equivalent to the two forces a d and dA, of which dA presses the ball on B at b, and produces the motion. In like manner, another ball E, so laid that b Be is obtuse, will fly off in the direction ED, which may even be opposite to Cc. These are matters of fact; not indeed precisely so, because billiard balls are not perfectly elastic, restoring their figure with a promptitude equal to that of their compression; and also because there is a little friction, by which the point a of the ball A is dragged a little in the direction of C's motion. This may both give a twirl to A, and diminish its pressure on B. The general result, however, is abundantly agreeable to the doctrines now delivered. But we wish to shew on what properties of tangible matter this depends; and although we dare not hope for implicit belief, we expect some credit in what we shall offer.

We have evident proof, that at a diffance which is Demonstras not unmeasurable by its minuteness, and certainly far tion. exceeds the 900th part of an inch, bodies repel each other with very great force. This distance also far exceeds the distance between the particles, if these are discrete. Let mn (fig. 3.) be the distance at which a particle repels another, and let P be a particle fituated at a less distance than ma from the surface AC of a folid body. With a radius PA, equal to mn, describe a fegment of a fphere ABC, and draw PB perpendicular to AC. It is plain, that every particle of matter in the fegment ABC repels the particle P, and that it is not affected by any more. Let D be any fuchparticle. It repels P in the direction DP. But there is another particle d fimilarly fituated on the other fide of PB. This will repel P with equal force in the direction dP. Therefore the two particles D and d will produce a joint repulsion in the direction BP. The like may be faid of every particle and its corresponding one on the other fide of PB. Therefore the joint re-

ibution int that Bruck.

I mpulsion pulsion of all the matter in the fegment will have the direction BP. It is plain, that the radius of curvature of every fensible figure may be confidered as immenfely great in comparison of mn; and therefore the proposition is manifest.

> This is a propolition of very great importance to the artist and the engineer, as well as to the philosopher. In all the connections of engines and machines, the mutual action is regulated by this fact. The mutual preffure at the contacts of the teeth of wheels and pinions depend so much on it, that it is easy to make them of fuch a shape that they shall produce no force whatever that is of any fervice; and it requires a skilled attention to their forms to obtain the fervice we want. This will be considered with some care in the article MA-

> Having thus discovered the direction of the real impulfion, and that it may be very different from that of the force exerted, we proceed to consider what will be the direction and velocity of the motion, and whether it will be accompanied with any rotation.

A ftroke, tion passes without rotation.

Our readers are acquainted with the elementary mechanical property of the centre of gravity. If a body through the be supported at this point by a force acting vertically centre of a upwards, and equal to the united weight of every parposition of ticle of matter in it, it will not only remain at rest, but folid body, will have no tendency to incline to either fide; that is, the upward force balances the weight of the whole body, and the mechanical momenta of all the heavy particles balance each other, like the weights in the scales of a steelyard. That this may be the case, we know that if the weight of every particle be multiplied into the horizontal lever by which it hangs (which is a line drawn from the particle perpendicular to a vertical plane passing through the centre of gravity), the sum of all the products on one fide must be equal to the sum of all the products on the other fide. Therefore, if we suppose the particles all equal, and represent each by unity, the fums of all the perpendiculars themselves must be equal. How is this balancing effected? Every particle tends downwards with a certain force. It must therefore be kept up by a force precifely equal and opposite. This must be propagated to the particle by means of the connecting corpufcular forces. The force propagated to any particle is equal and opposite to the force acting on that particle, which it balanced; and if not balanced, it would produce a motion equal and opposite to that produced by the other force. Gravity would cause every particle to descend equally; therefore the force which, by acting on one point, excites those balancing forces on each particle, would cause them to move equally upwards. And fince this is true in any attitude of the body, it follows, that a force, acting in any direction through the centre of gravity, will caufe all the particles to move in that direction equally; that is, without rotation.

Hence we learn, that when the direction of the stroke given to any body passes through the centre of gravity, the body will move in that direction without any rotation. If the quantity of matter, or number of equal particles in the body, be m, the moving power P will impress on each particle an accelerating force f, equal to the mth part of P. Therefore $f = \frac{P}{m}$, and P = mf.

An accelerating force is estimated by the velocity v,

which it generates by acting uniformly during some Impulsion. time t, or v = ft, and $f = \frac{v}{t}$, and $P = m \frac{v}{t}$, and

 $v = \frac{P}{m}t$. The fymbol t may be omitted, if we reck-

on every force by the velocity which it can produce in a second. Thus may all forces be compared with gravity, by taking 32 feet for the measure of gravity. Then mv will express the number of pounds which give a preffure equal to the force under confideration. Thus if the force can generate the velocity 48 feet per second in 100 pounds of matter, by acting on it uniformly during a fecond, its pressure is equal to the weight of 150 pounds.

When a body A, moving with the velocity a, over-This is ditakes or meets a body B, moving with the velocity b, red IMPUL and the line perpendicular to their touching furfaces ston. passes through the centres of both in the direction of their motion, all the circumstances of the collision arc determined by the rules already laid down. This is called DIRECT IMPULSE; and it is this which admits the application of the simple doctrines of impulsion, deduced, as we have done it, from the action of accelerating forces. All that was faid of the changes of motion produced in the magnets obtain here without any farther modification.

We may just be allowed to take notice of a curious observation of Mr Huyghens on the collision of perfectly elastic bodies. Instead of impelling the elastic ball C by the stroke of the elastic ball A, we may cause A to strike an intermediate ball B (also perfectly elastic), which is lying in contact with C. In many cases, the ball B will not flir fensibly from its place, and C alone will fly off. Nay, if a long row of equal billiard balls lie in contact, and one of the extreme balls be hit by another ball in the direction of the row, only the remote ball of the row will fly off. All this is eafily feen and understood, by considering them as bodies mutually repelling, and placed at the limits of their mutual action. Or even supposing them elastic balls, at a very fmall distance from each other: The ball employed to strike the first comes to rest, and the stricken ball moves off with its velocity: It strikes the second ball of the row, and is brought to rest: The second strikes the third, and is brought to rest: And this goes on in fuccession to the last, which is the only one that can fly off. The curious observation of Mr Huyghens is, that a greater velocity will be communicated by a large ball to a fmall one, if we employ the intermedium of another ball of a fize between the two; and that the velocity will be the greatest possible when the intermediate ball is a mean proportional (geometrical) between the two. This is also easily deduced from the similar attention to the action of the accelerating forces, or from the supposition of successive impulses. From this it also follows. that a greater velocity will be produced by the intervention of two, three, or more, mean pro-

But the direction of the stroke may not be the same Oblique IMwith that of the motion. This is called OBLIQUE IM. PULSION. PULSE. The cases of oblique collisions are extremely different, according to the directions of the motions; and the refults are, in many of them, far from being obvious. But we have not room for a particular treatment of them. We shall therefore avail ourselves of

pullion fome of the general facts mentioned above, by means fome point C of the line PG, and will also be perpen- Impulsion. of which we may reduce all the varieties to fome easy dicular to the same plane. All this has been demonstracases. The most serviceable general facts are: 1. That ted in the article ROTATION, nº 94. &c. Complete the actions of bodies on each other depend on their re- the parallelogram AFHE. It is plain, that the mobetive motions; and, 2. That the motion of the com- tion AH is equivalent to AE and AF. By the momon centre is not changed by the collision. These en- tion AE, A only slides along the surface of B without able us to reduce all to the case of a body in motion striking another at rest. We have only to determine their relative motion by the proposition in DYNAMICS, · nº 67. and then to superadd the common motion, which changes the relative into the true motions. Thus, if two bodies A and B (fig. 4.) meet in D, describing the lines AD, BD, the collision is the same as if B had remained at rest, and A had come against it with the motion AB. In the mean time, the common centre of position has described CD. If the bodies are unelastic, they remain united, and proceed in the line CD produced toward E, and their common velocity will be reprefented by DE, equal to CD, if AD and BD represented their initial velocities. If the bodies are elastic, they separate again, and they separate from the common centre in the opposite direction, and with the same velocities with which they approached it. Therefore draw a E b parallel to ACB, and make E a, E b equal to CA and CB, and then Da and Db are the paths and velocities of the bodies. All this is abundantly plain, and is a necessary deduction from the general principle, that the motion of the centre is not affected by any equal and opposite forces which connect the bodies of a fystem.

But this great simplicity is not sufficient for ascertaining the refults of collision which occur in many of the most important cases. It not only supposes that AD and ED are exactly proportional to the velocities of A and B, but also that they meet, so that the plane of mutual contact is perpendicular to the line AB, and that the stroke on each is directed to its centre. These circumstances will not always be combined, even in the case of spherical bodies. The consequence will be, that although the motion of the centre remains the fame, that of the bodies may fometimes be different. We must therefore give a general proposition, which will, with a little trouble, enable the reader to determine all the motions which can take place, whether pro-

greffive or rotative.

Let the body A (fig. 5.), moving with the velocity V, in the direction AD, strike the body B at rest. Let F be the point of mutual contact, and hFH a plane touching both bodies in F. Draw AFP perpendicular to this tangent plane, and through G, the centre of position of B, draw PGC perpendicular to FP, and GI parallel to FP. Let C, in the line PG, be the spontaneous centre of conversion (ROTATION, Encycl. no 77. &c.), corresponding to the point of percussion F. Join CF. Let the direction cut the tangent plane in H, and PF in A; and let AH represent the velocity V.

The impulse is made at the point F, in the direction AF or FP, and the centre of position of the body B will advance in the direction GI, parallel to FP, the direction of the effective impulse. But, because this does not pass through the centre G, the body will advance, and will also turn round an axis passing through G, perpendicular to the plane of the lines GP, PF, and the spontaneous axis of conversion will pass through Suppl. Vol. I. Part II.

pressing it, or causing any tendency to motion in that direction, except perhaps a little arising from friction. It is by the motion AF alone that the impulse is made.

Therefore let v be $= V \times \frac{AF}{AH}$; and then $A \times v$ may Efficient be called the efficient impulse of the body A in the pre-velocity. fent circumstances, and v the efficient velocity. This will be diminished by the collision. Let x be the unknown velocity remaining in A after the collision, or rather in the instant of the greatest compression and common motion of the touching points of A and B, estimated in the direction FP. The effective momentum lost by A must therefore be $A \times v - x$: but the same must be

gained by B, and its centre G must move in the direction GI, parallel to FP, with this momentum; and

therefore with the velocity $\frac{A \times v - x}{B}$. That this may be the case, the point of percussion F must yield with the velocity x, because the bodies are in contact. But because C is the spontaneous axis of conversion, every particle is beginning to describe an arch of a circle round this axis. Therefore F is beginning to move in the direction Fg, perpendicular to the momentary radius vector CF. Let Fg be a very minute arch, described in a moment of time. Draw gf perpendicular to FP. Then Ff is the motion Fg reduced to the direction FP, and will express the yielding of B in the direction of the impulse, while G describes a space

equal to $\frac{A \times v - x}{B}$, and A describes a space x. There-

fore Fg will express x. Let Pp be the space described in the same time that Fg is described. Draw pC, cutting GK in the point I. GI is the yielding of the body B to

the impulse, and must therefore be equal to $\frac{A \times v - x}{B}$.

The triangles Ffg and CPF are fimilar; for the angle CFP is the complement of fFg to a right angle: angle CFP is the complement of f F g to a right angle: It is also the complement of PCF to a right angle. Therefore F g : F f = FC : CP. But F g : P p = FC : CP; because the little arches F g, P p have the same angle at C. Therefore P p = F f, = x. It is plain, that CG : CP = GI : P p. Therefore $CG : CP = \frac{A \times v - x}{B} : x$, and $x = \frac{A \times v - x \times CP}{B \times CG}$, or $x = \frac{A \times CP}{B \times CG} - x \times \frac{A \times CP}{B \times CG}$; wherefore

$$= \frac{A \times v - x}{B} : x, \text{ and } x = \frac{A \times v - x \times CP}{B \times CG}, \text{ or } x$$

 $x \times B \times CG + x \times A \times CP = v \times A \times CP$, and $x \times B \times CG + A \times CP = v \times A \times CP$, and $A \times CP$ $x = v \times B \times CG + A \times CP$, $x = v \times CP$, x =

Unclastic

ing in A, estimated in the direction FP. And u, the velocity with which G will advance, is separate.

 $\frac{CC}{CP}$; for CP : CC = Pp : GI, = s : u. It is

evident that A will change its direction by the collision: For in the instant of greatest compression, it was react-

69 en acupanied rota-

neral corem.

Impulsion, ed on by a force $= A \times v - x$ in the direction FA. This must be compounded with A X V, in the direction AH, in order to obtain the new motion of A; or it may be found by compounding x, which is retained by A, with FH, which has suffered no change by the collifion. The bodies will therefore separate, although they be unelastic: If they are elastic, we must double these changes on each. If B was also in motion before the collision, the motion of A must be resolved into two, one of which is equal and parallel to the motion of B: the other must be employed as we have employed the motion AH.

Expressions still more general may be obtained for x and u; namely, by taking the formulæ for the centres. of conversion and percussion (ROTATION, nº 96, 99.)

 $CG = \frac{\int p r^2}{B \times GP}$, and $CP = \frac{\int p r^2 + B \times CP}{B \times GP}$,

where p stands for a Particle of matter, and r for its distance from an axis passing through G perpendicularly to the plane of the lines GP and PF. In this way

we obtain $n = v \frac{A \cdot \int p \, r^2 + A \cdot B \cdot GP^2}{A + B \cdot \int p \, r^2 + A \cdot B \cdot GP^2}$

It is plain from this proposition, that the progressive Change of progressive motion of the body depends, not only on the momentum of the impelling body, but also on the place where motion greateft the other is struck: For even although the original mowhen the direction of mentum of A be the same, and the obliquity of the stroke, making v the same, and the body (and consepasses thro' quently /pr') also remain the same, we see that x and

the centres. u depend on the ratio of CP to CG. Now C and P are always on opposite sides of G: Consequently, by removing the direction FP of the impulsion farther from G, we diminish CG and increase CP; and there-

-fore increase the value of $x = v \frac{1}{B \cdot CG + A \cdot CP}$; and

consequently diminish the value of $A \times v - \kappa$, to which B x u is equal. The greatest momentum of B is produced when the direction of the impulse passes through G, and no rotation is produced. Indeed we are led,

by a fort of common sense, to expect this.

This investigation is by no means a piece of mere Importance fpeculative curiofity. It is the folution of the greatest of this theory to sea- problem in practical mechanics. It is in this way that we must proceed in computing the actions of the wind and water on the fails and hull of a ship. Were it not that many circumstances concur in determining several of the preparatory steps, it is evident that the task must be almost impracticable. But the pressure and its direction are generally determined by experiment, without the trouble of computation; and we are feldom folicitous about the subsequent motion of the wind or

Impulsion on hodies lar paths.

There is another question in impulsion which is of the first practical importance—namely, when the impulse is exerted on the parts of a machine, where the to particu- body struck is not at liberty to yield freely to the stroke, but must slide along some solid path, or turn round fome axis, or take fome other constrained motion. The operations of most engines depend on this. The operation of wedges, axes, and many cutting and piercing instruments, and the penetration of piles, im-

pelled by a rammer, are all afcertained by the same Impulsions doctrines. But the particular applications can scarcely be elucidated by any classification that occurs to us, the circumstances of the case making such great difference in the refult, both in kind and degree. For example, in the funplest case that occurs, the driving of piles, the penetration of the pile depends, in the first place, on the momentum of the rammer. If the mass of the pile be neglected, the penetration through a uniformly resisting substance will be as the square of the velocity of the rammer, (DYNAMICS, Suppl. nº 05), and its absolute quantity may be determined from a knowledge of the proportion of the weight of the rammer to the refistance of the earth. But when we confider that we have to put in motion the whole matter of the pile, we learn that a great diminution of the effect must take place. We still can compute what this must be, because we have the same momentum, with a velocity diminished in a certain proportion of the sum of the matter in the rammer and pile, to that in the rammer alone. - Another defalcation arises from friction, which continually increases as the pile goes deeper;and a still greater defalcation proceeds from the nature of the pile. If it is a piece of very dry straight grained fir, it is very elastic, and acquires almost a double velocity from the stroke of a rammer of cast iron. If it is moist and soft, especially if it is oak, or other timber of an undulated fibre, it does not acquire fo great velocity, and the penetration is very much diminished. It is probable that a pile, headed with moist cork, could not be driven at all. The writer of this article found a remarkable effect of the elasticity in the process of boring limestone. When the boring bit was made entirely of ficel, and tempered through its whole length to a hard spring temper, the workman bored three inches, in the same time that another bored two inches with a bit made of foft iron; and he would never use any but steel bits, if they could be hindered from chipping by the liammer (which must also be of tempered steel throughout). This has hitherto baffled many actempts. A pretty large round head, like a marlin spike, has succeeded best: but even this cracks after some days use. The improvement is richly worth attention; for the workman is delighted by feeling the hammer rife in his hand after every flroke, and fays that the work is not fo hard by half. N.B. The stone cutters at Lisbon and Oporto use iron mallets.

The case of impulsion made on part of a machine Impulsion moveable round an axis has been considered in the ar-on maticle ROTATION, Encycl. no 72; where x is shewn to chines.

be = $v \times \frac{A. C P^2}{\int p r^3 + A. C P^2}$. But, in this formula, r denotes the diffance of p from the point C, and not from

G. fpr' in this formula, is B. CG. CP; whereas, in the formula for a free body, where r is the distance of

a particle from G, $\int p r^2$ is = B. CG. GP.

In the practical confideration of this question, the reader will do well to confider the whole of that article with attention. Many circumstances occur, which make a proper choice of the point of impulse, and the direction of the tangent plane, of the greatest consequence to the good performance of the machine; and

Populsion, there is nothing in which the scientific knowledge of given by a falling body with the pressure of a weight Impulsion. that can enable him to communicate his knowledge to others, or even secure himself against 'all mistakes; real mechanics, may be applied with fafety on all occafions, because arithmetical computations, when rightly made, afford the most certain of all results.

Great lofs of power by the yielding and bending of the

There is a circumstance which greatly affects the performance of machines which are actuated by impulses, namely, the yielding and bending of the parts. When the moving power acts by repeated small impulsions, it may fometimes be entirely confumed, without produmateriale. cing any effect whatever at the remote working point of the machine; and the engineer, who founds his constructions on the elementary theories to be had in most treatises of mechanics, will often be miserably disappointed. In the usual theories, even as delivered by writers of eminence, it is afferted, that the smallest impulse will start the greatest weight. But fince impulse is only a continued pressure, and requires time for the transmission of its effect through the parts of a yielding folid, it is plain that the motion of the impelling body may be extinguished before it has produced compresfion enough for exciting the forces which are to raife the remote parts of a heavy body from the ground. What blow with a hammer could ftart a feather bed? Much oftener may we expect, that a blow, given to one arm of a long lever, will be confumed in bending the whole of its length, so as to bring the remote end into action. Therefore great stiffness, and perfect elaflicity, both in the moving parts and in the points of support, are necessary for transmitting the full, or even a confiderable part, of the power of the impelling body. Perhaps not the half of the blow given by the wipers of a great forge or tilting mill to the shank of the hammer is transmitted in the proper instant of time to the hammer-head. The hammer, while it is toffed up by the blow, is quivering as it flies. Should it reach the spring above it in the time of its downward vibration, it will not be returned with such force as if it had hit the spring a moment before or after. A quarter of an inch will produce a great effect in such cases. It is found, that the minute impulses given to the pallets of a clock or watch lofe much of their force by the imperfect elasticity of the pendulum or balance: We must therefore make all the parts which transmit the blow to the regulating mass of matter as continuous, ruby pallets is very fenfibly, weakened by putting oil on the face of them, especially in the detached scapements, which act partly by impulse. A wheel of hard tempered fteel, working on a dry ruby pallet; excels all others. The intelligent engineer, feeing that, after all his care, much impulsion is unavoidably loft, will avoid employing a first mover which acts in a subsultory manner, and will substitute one of continued pressure when it is in his power. This is one chief cause of the great superiority of overshot water wheels above the undershot.

the engineer is of more effential fervice to him. An in the opposite scale of a balance, and can see the reaengineer of great practice, and a fagacious combining fon of the immense differences, yet accompanied by a mind, collects his general observations, and stores them fort of regularity, in the results of the experiments. Gaup as rules of future practice. But it is feldom that lileo, Mersennus, and Riccioli, found them to be proofehe possesses them with that distinctness and considence that the forces of moving bodies are as their velocities: because the heights from which the body fell were as the squares of the weights started from the ground. Gravewhereas a moderate acquaintance with these elements of sande found the same thing as long as he held the same opinion; but when he adopted the Leibnitzian measure. he found many faults in the apparatus employed in his former illustrations, and altered it, till he obtained refults agreeable to his new creed. But any one who examines with attention all that passes in the bending of the apparatus, and takes into account the mass of matter which must be displaced before the opposite arm rifes fo far as to detach the spring which gives indication of the magnitude of the stroke, must see that the agreement is purely accidental, and may be procured for any theory we please (see Gravefande's Nat. Phil. translated by Desaguiliers, vol. i. p. 241. &c.). The proposition, nº 95, Dynamics, suffices for explaining every thing that can happen in such experiments. And it will shew us, that although the motion of impulsion is produced by pressure alone, yet impulse is incomparable with mere pressure: It is not infinitely greater, but disparate. A weight (which is a pressure) bends a spring to a certain degree, and will derange to a certain degree the fibres of a body on which it presses, before it be balanced. The same weight, falling on this spring from the smallest height, will bend it farther, and may crush or shiver to pieces the body which would have carried it for ever. We shall make some further remarks. on this subject, of great practical importance, under the word Percussion.

THE method which we have purfued in confidering Co verte the doctrines of impulsion, differs considerably from that SION. which has generally been followed; but we trust that it will not be found the less instructive. Although the reader should not adopt our decided opinion, that we have no proof of pure impulsion ever being obferved, and that all the phenomena which go by that name are really the effects of pressures, analogous to gravity, he perceives that our opinion does not lead to any general laws of impulsion that are different from those which are acknowledged by all. We differ only, by exhibiting the internal procedure by which they are unquestionably produced in a vast number of cases, and which takes place in all that we have feen, in some degree. Our method has undoubtedly this advantage, that it requires no principle but one, namely, hard, elastic, and stiff, as possible. The performance of -that accelerating forces are to be estimated by the acceleration which they produce. Even this may be confidered, not as a principle, but merely as a defini-tion—We get rid of all the obscurity and perplexity that refult from the introduction of inertia, confidered as a power-a power of doing nothing-and we are freed from the unphilosophical fiction (adopted by all the abettors of that doctrine, and even by many others) of conceiving the space, in which motions are performed, and bodies act, to be earried along with the bodies in it .- This furnishes, indeed, in some cases, a familiar We can now understand how it happens that Gal-, way of conceiving the thing, by supposing the experilileo, Mersennus, and others, could compare the impulse ments to be made in a ship under sail, and by appealEmpulsion, ing to the fact, that all our experiments are made on the surface of a globe that is moving with a very great ment, par Jean Bernoulli, Paris, 1727. velocity. But it is an abfurdity in philosophy, and, when minutely or argumentatively used, it does not free us from one complication of action; for, before we can make use of this substitution, we must demonstrate, that the actions depend on the relative motions only: And this, when demonstrated, obliges us to measure forces by the velocity which they produce.

As no part of mechanical philosophy has been so much debated about as impulsion; it will furely be agreeable to our readers to have a notice of the different treatifes which have been published on the subject :

No 479. - Alfo Gravesande's Nat. Philosophy, where there is a most laborious collection of experiments and reasonings; all of which receive a complete explanation by the 39th Prop. Princip. Neutoni I. or our no 95. DYNAMICS. There are also many very acute philosophical observations in Lambert's Gedanken iber die Grundlehren des Gleichgewichts, und der Bewegung. in the second part of his Gebrauch der Mathematik.-Also, in the works of Kaestner, Hamberger, and Busch. Muschenbroeck also treats the subject at great length, but not very judiciously. We do not know any work which treats it with fuch perspicuous brevity as M'Laurin's Account of Newton's Philosophy.

END OF THE FIRST VOLUME.

ERR'ATA.

Page 108. col. 1. Dele lines 24, 25, 26, 27, 28, 29; and in their place read, "which though Lord Auchinleck and his fon took the same fide, they took it with very different degrees of ardour. The " judge faw not the propriety of illuminating his windows, when the cause was finally decided by the "House of Peers; and to compel him to illuminate, the advocate got possession of a Chinese gong. Page 186. col. 1. line 18. For "Henry VI." read "Henry II."

253. col. 1. line 23. for sulphuret read sulphat.

CHEMISTRY-Index, page 399. col. 1. line 2. After 464 add, "and Part 3. chap. 2. fect. 11. Page 399. col. 1. line 38. For p. 624, read 359. - Page 400, col- 2. line 18. For p. 624. read p. 359. Page 451. col. 1. line 34. For "Diderot," read "D'Alembert."
